If there is one thing certain in the Kantian philosophy, it is that the object of perception is that which is contributed by mind must not be extended to things beyond mind. Hegel only extended a priori to things by resolving things into thoughts. Mill also protested against adumbrating, as evidence of the truth of a fact in external nature, the disposition, however strong or however general, of the human mind to believe it. Yet Martinang adopted, as his view of the limits of human intelligence, that Kant was right in making space and time a priori forms of sense, but wrong in limiting them to sensations. But in order to make space a form of external things, Martinang had to take the external in space, by which Kant meant one sensation out of another, in the very different meaning of the self here and the self there. He facilitated this awkward transition by adding to Kant's a priori forms of space and time an "a priori form of causality," as he called it, "the condition of the external system of causality involved in the elementary exercise of perception," which is the key to his whole philosophy. He supposed that this intuition of causality arises when will is resisted, and, further supposing that causality requires decision between alternatives, concluded that the intuition of will resisted is an intuition of will against will, mine against other (I. 65). To pass over its confusion of a priori and intuitive, there are two fatal objections to this view. In the first place, the intuition of causality does not require will at all, because we often perceive one bodily member pressing another involuntarily; a man suffering from lockjaw neither wills nor can avoid the feeling of pressure of his upper and lower jaws against each other. Secondly, though causality requires alternatives in the material cause, e.g., wax may or may not be melted, the determination between them is not always a decision of will, but in physical causation depends on the efficient cause, e.g., fire: an instance like that of Spence; according indeed, more the active and passive powers approach, the one must act, and the other suffer, and it is only in rational powers that will decides (Met. Θ 5).

A. J. Balfour, in The Foundations of Belief, being Notes Introd. to the Study of Theology (1895), begins by maintaining that the evidence of the senses is not a foundation of belief, and then expects us to believe in Nature and in God. He revives the "Acatalepsia" of the New Academy. In Part II., ch. i., he makes three assumptions about the senses, and, without stopping to prove them, or even to make them consist, deduces from them his thesis that the evidence of the senses is not a foundation of belief in Nature. He first assumes an immediate experience of a body, e.g., a green tree; and then deduces that the evidence of the senses proves now and then to be fallacious, because we may have an experience indistinguishable from that of a tree but incorrect; and again that our perceptions are habitually mendacious, because all visual experiences are erroneous, as colour is a sensation while the thing consists of uncoloured particles. This argument from a pure assumption is a confusion of sense and inference. In no case is the evidence of the senses fallacious or mendacious; the fallacy is in the inference.

He next assumes that we have no immediate experience of independent things—that sense perceives sensations, feelings, or ideas; while all else, e.g., a tree, is a matter of inference. On this quite new assumption of a sense of sensations he deduces that, from a perception of these mental facts, we could not infer material facts, e.g., a tree; so that again the evidence of the senses does not afford trustworthy knowledge of the material universe. His deduction is logical; but he has forgotten to prove the assumption, and now confuses sensory operation with sensible object. Vision does not perceive a sensation of colour; it perceives a visible picture, e.g., green, which is in the organism, but has never been proved to be a mental fact, or not to be a material fact. So touch perceives not a sensation of pressure, but a pressure which is a material fact in the organism. From a material pressure within we logically infer a material pressure outside. He thirdly assumes an appendix to the second assumption: he assumes that sense perceives mental sensations with succession, but without causality, because no kind of cause is open to observation. On this assumption of a sense of sensations, but not of causality, he deduces that we could not from such data infer any particular kind of cause, or a bodily cause, e.g., a tree, or indeed any cause at all, or any event beyond perception, without assuming the principle of causation that Nature is uniform in cause and effect over great intervals of time and space. Nevertheless he gives absolutely no proof of the assumption that there is no sense of causality. There is none in the subsidiary senses, because none of them perceives the pressures exerted on them. But the primary sense of touch perceives one bodily member causing pressure on another, reciprocally, within the organism, from which we infer similar particular pressures caused between the organism and the external world; but without needing the supposed stupendous belief and assumption of the uniformity of Nature, which is altogether ignored by the inference. Sense of the tree receives reciprocal pressure within, and tactile inference infers it without, touch is the primary evidence of the senses which is the foundation and logical ground of our belief in Nature as a system of pressing bodies. Balfour, however, having from unproved assumptions denied the evidence of the senses, and the rational power of using them to infer things beyond oneself, has to look out for other, and non-rational, foundations of belief. He finds them in the needs of man. According to him, we believe in Nature because it satisfies our material needs, and in God because he satisfies our spiritual needs. But bare need, e.g., a pang of hunger, is no cause of belief beyond itself; and desire, or need of something prospective, e.g., a desire of food, is effect, not cause, of a previous belief that there is such a thing, and of a present inference that it may again be realized. Moreover, when the belief or inference is uncertain, need even in the shape of desire is not in itself a foundation of belief in the thing desired: to be desired is not to believe in getting it; and, as Aristotle said, "there is a wish for impossibilities." It is fair, however, to add that Balfour has a further foundation for the belief in Nature, the survival of the fittest, by which those only would survive who possessed and could transmit the belief. But here he fails exactly as Darwin himself failed. Darwin said, given that organisms are fit, they will tend to survive; but he failed to show how they become fit. Balfour says, given that men believe in Nature, they will survive; but he fails to show how they come to believe in it. Inference from sense is the one condition of all belief in anything beyond oneself, whether it be Nature, or Authority, or God; and it is the one condition of all needs, which are not mere feelings, but desires of things. The result of undermining this sure foundation emerges in Balfour's attitude to the beliefs themselves. He holds that space, time, matter, motion, force, are all full of the insoluble contradictions supposed by Spencer; and that all our beliefs, in Nature and God, stand on the same footing of approximations. Hence his really valuable arguments from Nature to God sink to the problematic form—there may be Nature; if so, there is God.
Such is the modern "Acatalepsia," which arises from denying the evidence of the senses, and from citing the transfigured realism of Spencer instead of the original realism of Aristotle, about whom Balfour speaks as follows: "It would be difficult, perhaps impossible, to sum up our debts to Aristotle. But assuredly they do not include a tenable doctrine of the universe."

4. The Past and Future of Metaphysics.—Aristotelian realism is the strong point of Roman Catholic philosophy. As interpreted by Thomas Aquinas, it is now in danger of becoming a dogma. In 1879 Pope Leo XIII. addressed to the bishops the Encyclical aeterni patris, which contained the words, "Sancti Thomae sapientiam restitutis et quam latissime propagatet." From the Roman Catholic point of view this reaction to "Thomism" was a timely protest against modern metaphysics. It was founded upon a feeling of uneasiness at a growing tendency among Roman Catholic writers not only to treat theology, freely but to criticize it by paradoxes. One cannot but feel regret at seeing the Reformed Churches blown about by every wind of doctrine, and catching at straws now from Kant, now from Hegel, and now from Lotze, or at home from Green, Caird, Martineau, Balfour and Ward in succession, without ever having considered the making of their faith; while the Roman Catholics are making every effort to ground a Universal Church on a sane system of metaphysics. However this may be, the power of the movement is visible enough from the spread of Thomism over the civilized world, and in England from the difference between the freer treatment of metaphysics by some Roman Catholic writers and that which has arisen under the immediate influence of Thomism. J. H. Newman (1801-1890), maintaining the authority of conscience and the probabilism of the understanding, concluded to the necessity of a higher authority in the matter of metaphysics, and was a philosophical critic of Mill. St George Mivart, in The Ground-work of Science (1888), maintained the reality of an active causative power underlying Nature, and the dignity of human reason, from an independent point of view. On the other hand, more under the influence of the Thomist reaction, Thomas Harper published The Metaphysics of the School (1879, &c.), describing scholasticism, as it appears in the works of Aquinas; and The Manuals of Catholic Philosophy, edited by R. F. Clarke, include General Metaphysics (1890), by John Rickaby, who effectively criticizes Hegel by precise distinctions, which, though scholastic, did not deserve to be forgotten.

The Thomist reaction has had a good effect in the way of encouraging the study of Aristotelian philosophy in itself, and as modified by Aquinas. Nevertheless, the world cannot afford to surrender the use of a great force, such as purely philosophical, about Nature to understand its matter, or its motions, or its forces; and consequently he fell into the error of supposing a primary matter with four contrary primary qualities, dry, hard, earth, water, fire, and earth, air and fire, with natural rectilinear motions to or from the centre of the earth; to which he added a quintessence of ether composing the stars, with a natural circular motion. Consequently, in the Metaphysics, the primary matter was often supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural substance or body is a concrete whole, independent and uniform, and emergent from the first, and that besides proximate matter, or one body as matter of another, there is a primary formless matter beneath all bodies, capable of becoming all in turn, but itself potentially, not actually, substance. He thought not only that a form, or substance, W. G. Ward was a pupil of Herbert Spencer, and he supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural substance or body is a concrete whole, independent and uniform, and emergent from the first, and that besides proximate matter, or one body as matter of another, there is a primary formless matter beneath all bodies, capable of becoming all in turn, but itself potentially, not actually, substance. He thought not only that a form, or substance, W. G. Ward was a pupil of Herbert Spencer, and he supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural substance or body is a concrete whole, independent and uniform, and emergent from the first, and that besides proximate matter, or one body as matter of another, there is a primary formless matter beneath all bodies, capable of becoming all in turn, but itself potentially, not actually, substance. He thought not only that a form, or substance, W. G. Ward was a pupil of Herbert Spencer, and he supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural substance or body is a concrete whole, independent and uniform, and emergent from the first, and that besides proximate matter, or one body as matter of another, there is a primary formless matter beneath all bodies, capable of becoming all in turn, but itself potentially, not actually, substance. He thought not only that a form, or substance, W. G. METAPONTUM—METASOMATISM

METAPONTUM (Gr. Μεταπόντιον, mod. Metaponto), an ancient city of Magna Graecia situated on the Gulf of Tarentum, near the mouth of the river Bradanus, and distant about 24 m. from Tarentum and 14 m. from Herculaneum. It was founded by an Achaean colony from Sybaris and Crotona about 700 B.C. Metapontum was one of the cities that played a conspicuous part in the troubles arising from the introduction of the Pythagoreanism into Magna Graecia, and it was there that Pythagoras died in 497 B.C. His tomb was still shown in the time of Cicero.

At the time of the Athenian expedition to Sicily (415 B.C.) Metapontum appears to have been an opulent and powerful city, whose alliance was courted by the Athenians; but it contented itself with a very trilling support. In 332 B.C., at the time of the expedition of Alexander, king of Epirus, into Italy, it was one of the first cities to enter into an alliance with him. The Second Punic War gave a fatal blow to its prosperity. After the battle of Cannae in 216 B.C. it was among the first cities in the south of Italy to declare in favour of Hannibal, and became for some years the headquarters of Hannibal. Hence, when the defeat of Hasdrubal at the Metaurus (207 B.C.) compelled him to abandon this part of Italy, the inhabitants of Metapontum abandoned their city, and followed him in his retreat.

From this time Metapontum sank; though it was still existing in the days of Cicero, Pausanias tells us that in his time nothing remained of it but a theatre and the circuit of the walls.

Metapontum has the remains of two temples, both of which seem to belong to the period 510-480 B.C. (Koldewe and Puchstein, Die griechischen Tempel in Unteritalien und Sicilien, Berlin, 1896, pp. 35-41). The so-called Chiesa di Sansone, which lay within the ancient town, and was probably dedicated to Apollo Lyceus, was a peripteral measuring 186 by 91 1/3 ft., of which only the foundations are left. The capitals were 38 ft. in diameter. The temple was decorated with finely painted terra-cottas. Of the second temple, the so-called Tavole Cave, which lay outside the area of the ancient city, and was a peripteral with 6 columns, 35 ft. in diameter, in front and 12 ft. at the sides, 16 columns are standing, with the lower portion of the epistyle. It measured 105 ft. by 49 ft. without the steps. There are also traces of the town walls, which have served for the construction of farmhouses, of tombs, and of a harbour by the shore. Pliny speaks of a temple of Juno at Metapontum supported by columns of vinewood (Hist. nat. xiv. 9). An archaic treasure-house dedicated at Olympia by the people of Metapontum has been discovered there. The railway station is the junction of the line from Battipaglia (and Naples) with that from Taranto to Reggio.

METASOMATISM (Gr. μετά, change, σώµα, body), in petrology, a process of alteration of rocks by which their chemical composition is modified, new substances being introduced while those originally present are partly or wholly removed in solution. For example a limestone may be converted into a siliceous chalk, a dolomite, an ironstone, or a mass of metallic ores by metasomatic alteration. The process is usually incomplete, greater or smaller portions of the original rock remaining. The agencies of the metasomatism are in nearly all cases aqueous solutions; probably they were often at a high temperature, as metasomatic changes are especially liable to occur in the vicinity of igneous intrusions (laccoliths, dikes and necks) where large quantities of water were given off by the volcanic magma at a time when it had solidified but was not yet cold. Metasomatism also usually goes on at some depth, so that we may readily believe that it is favoured by increase of pressure. On the other hand, there was a considerable instance in which these processes cannot be shown to have taken place at temperatures or pressures above those which normally exist in the upper part of the earth's crust (e.g. dolomitization and silicification of many limestones). There are also cases of metasomatism in which steam and other vapours are supposed to have been operative; the temperatures were probably above the critical temperature of water. Changes of this sort are described as pneumatolytic, being induced by gases (see PNEUMATOLYSIS).

By metasomatism new minerals replace the primitive ones; at the same time the original rock-structures may be completely obliterated. An igneous rock for example may be entirely replaced by crystalline massive quartz, a fossiliferous limestone by granular crystalline dolomite. It is equally common, however, to find that the structure of the original rock is preserved though its substance has been entirely altered. An oolitic limestone may become an oolitic ironstone or chert (see PETROLOGY, PI. IV. fig. 5.) and casts of the fossils which the limestone contained may be formed of siderite or of chalcedony. In this case the rock resembles a pseudomorph, which is the term applied to a mineral which has been entirely replaced by another mineral without losing its original crystalline form. As a result of metasomatism rocks usually become more crystalline, especially those which have been in large part built up of fossil organic remains; this is a consequence in the new substances having been deposited by purely inorganic processes from solution in water.

The chemical change is often complete, as when a limestone is replaced by chert or otherwise silicified, but it is probably more usually incomplete, part of the substance of the original rock having been retained though possibly in new mineral combinations. When a limestone is replaced by ironstone (e.g. carbonate of iron or siderite) part at least of the carbonic acid may be that of the limestone. A dolomite, formed from a limestone, contains more than one-half of its weight of carbonate of lime presumably derived from the limestone itself; yet in this case the mineral transformation may be perfect, as the dolomite retains none of the calcite of which the limestone was formed; it is all present as the double carbonate of lime and magnesia (or dolomite). When a granite is converted by emanations contained in a quartz-mica rock (gneiss rock, q.v.) or a quartz-mica rock (greisen, q.v.) it can be proved by analysis that there has been very little modification of the chemical composition of the original mass. This resembles parasitism in minerals, in which one mineral is substituted for another having the same chemical composition (e.g. kyanite for andalusite).

The relations between metamorphism and metasomatism are very close; in fact some authors regard metasomatism as a variety of metamorphism. It is generally true, however, that in metamorphic changes there is little chemical alteration; sandstones pass into shales without any essential change, marbles and gneisses, limestones into marls without any essential modification in chemical composition, for the original minerals new ones being substituted and new structures being produced at the same time. In metasomatism, on the other hand, chemical alteration is supposed by most geologists to be an essential feature; new minerals appear, but the original structures are sometimes retained.

The facility with which a rock undergoes metasomatism depends partly on its mineral composition, the ease with which the elements in it are replaced. Limestones, being readily soluble under natural conditions, are especially liable. The Cleveland iron ores of Yorkshire are limestones replaced by siderite and limonite; the Whitehaven iron ores are metasomatic replacements of limestone by haematite. The former are of Mesozoic, the latter of Palaeozoic age, but both have been changed in very much the same way by percolating solutions containing salts of iron. In some cases limonite and magnetite may occur. Carboniferous limestones have been taken to very irregularly, along bedding planes, faults and fractures. An ironstone may in many places be traced laterally into a limestone, the amount of iron in the rock gradually diminishing. Some ironstones (Carboniferous, Jurassic, &c.) represent former limestone structures intercalated among the limestones they usually show little change, a fact which indicates that the ready solubility of the limestone is counteracted by the iron deposits. It is believed that the Whitehaven iron ores may be derived from the ironstones of the Coal-Measures which once covered the limestone district.

Dolomitization of limestones is even more common than replacement by iron ores. That it is going on at the present day is evident from the fact that cores obtained by boring in recent coral reefs have shown that these may be extensively dolomitized in their deeper parts, and the older limestones such as the Triassic of the Alps, the Carboniferous Limestone of England and the Cambrian
Limestone of Scotland are sometimes converted into dolomite over wide areas. There has been an introduction of magnesia, with sometimes a little silica and iron; the rock recrystallizes owing to the formation of small rhombohedra of dolomite; it frequently becomes disseminated with banding and the limestones containing siderite in volume which takes place, and the fossils and other organic structures of the original rock disappear. The change proceeds outwards from fissures and bedding planes and spreads gradually through the rock. The limestone then becomes a complete and unaltered rock. Silification or the replacement of limestone by chaledony, chert or quartz, is often exhibited on a large scale. The formation of thin nodules and chatter bands and a thin siliceous layer may be an indication of a replacement without, but is merely the material of the fine siliceous skeletons of sponges, radiolaria and other organisms, which at first were widely scattered through the limestone and at a later time were dissolved by percolation and water. They are often of a brownish red and in certain situations as bands, nodules and tabular masses of crypto-crystalline silica. In limestones extensive deposits of zinc ore may occur, usually calcite. These are important sources of the metal and are often more in demand than they have formed by a process of metasomatic replacement, e.g. Carthage, Raiß in Carinthia and Belgium. In many parts of western North America (Nevada, Arizona, &c.) great deposits of copper, lead and silver ores are worked in crystalline limestones. They are often highly silicified, and as-sociated with iron ores, as well as with carbonaceous slate, adacite, porphyry and diabase. The ores occur not only in veins and shoots, but also in great masses replacing the limestone, and the geologists who have examined these mining districts are nearly unanimous in attributing to the metasomatic action of the copper ores a large part of the origin of the silver deposits. Other rocks such as tuff, volcanic breccia, shale, porphyry and granite may also be impregnated with metalliciferous ores, but the largest ore bodies are found in the limestones. Secondary enrichment of the ores may be produced by the hydrothermal action, and the constant presence of igneous rocks indicates that they are connected with the introduction of the metals, and the deposits are often of such a kind as to show that post-volcanic discharges of magmatic gases may have played a large part in their formation. Bishop Clifton and the Globe district in Arizona, Flagstaff in Utah, and the Eureka district in Nevada are good examples of the deposits in question.

As indicated above, shales, sandstones and igneous rocks may be silicified and mineralized under suitable conditions. Rhyolites and rhyolitic tuffs are often impregnated with silica to such an extent that they become almost massive quartz, and the fluid, porphyritic, sandstones, greywacke and other igneous rocks on a plate of the original rock may be retained in the silaceous pseudomorph. There are many examples of this in North Wales and the Pentland Hills. In andesites, serpentines and trachytes silicification is frequently found in circumstances indicating that the changes are not due to weathering but are the result of post-volcanic emanations of heated waters. Silicified shales may accompany mineral deposits, e.g. in the Cornish tin mines the killas or grey slate may be converted into quartz and brown tourmaline; greywacke and shales and the actual mineralizing agents of such copper mines as Parys Mountain, Anglesey, formerly of great importance as producers of this metal, there are large areas of silicified slate and silicified porphyry. White mica, kaolin, gilsonite, siderite and other deposits are also produced in connection with igneous rocks. As a further instance of mineral deposition in metasomatized igneous rocks we may quote the Cripple Creek goldfield in Colorado, where syenites, lattes, phonolites, breccias, &c., have been replaced by calcite, fluorite, calaverite and other new minerals together with quartz.

Another type of metasomatic alteration is phosphatization. This is most common in limestones, and many of the most important leaded phosphate deposits are of this origin. Trachytes and other igneous rocks are occasionally phosphatized. The phosphates are the most part the skeletons of animals, vertebrate bones and teeth, shells of certain brachiopods, trilobites and other groups. Guano, the excreta of birds, is rich in phosphates and these are washed out by rainwater and form metasomatic changes in the underlying rocks. Phosphatized limestones are obtained in great quantities in Christmas Island, Sombrero, Curaçao and other uninhabited limestone islands.

**METASTASIO** (1698–1782) Pietro Trappassi, the Italian poet who is better known by his assumed name of Metastasio, was born in Rome on the 13th of January 1698. His father, Felice Trappassi, a native of Assisi, came to Rome and took service in the Corsican regiment of the papal forces. He subsequently married a Bolognese woman, called Francesca Galasti, and established himself in business as a grocer in the Via dei Cappellari. Married two sons and two daughters were the fruit of this marriage. The eldest son, Leopoldo, must be mentioned, since he played a part of some importance in the poet’s life. Pietro, while quite a child, often held a crowd attentive in the streets while he recited impromptu verses on a given subject. It so happened that, while he was thus engaged one evening in the year 1700, two men of distinction in Roman society stopped to listen to his declamation. These were Gian Vincenzo Gravina, famous for legal and literary erudition, famous for his dictation of the Arcadian Academy, and Lorenzini, a critic of some note. Gravina was at once attracted by the boy’s poetical talent and charm of person, interested himself in the genius he had accidentally discovered, made Pietro his protegé, and in the course of a few weeks adopted him. Felice Trappassi was glad enough to give his son the chance of a good education and introduction into the world under auspices so favourable. Gravina hellenized the boy’s name Trappassi into Metastasio; and introduced his adopted son to be a jurist like himself. He therefore made the boy learn Latin and begin the study of law. At the same time he cultivated his literary gifts, and displayed the youthful prodigy both at his own house and in the Roman coteries. Metastasio soon found himself competing with the most celebrated improvisator of his time in Italy. Days spent in severe studies, evenings devoted to the task of improvising sixty stanzas at a single session, were fast ruining Pietro’s health and straining his poetic faculties. At this moment Gravina had to journey to Calabria on business. He took Metastasio with him, exhibited him in the literary circles of Naples, and then placed him under the care of his kinsman Gregorio Caroprese at a little place called Scalea. In country air and the quiet of the southern seashore Metastasio’s health revived. It was decreed by Gravina that he should never improvise again, but should be reserved for nobler efforts, when, having completed his education, he might enter into competition with the greatest poets.

Metastasio responded to his patron’s wishes. At the age of twelve he translated the Iliad into octave stanzas; and two years later he composed a tragedy in the manner of Seneca upon a subject chosen from Trissino’s Italia liberata — Gravina’s favourite epic. It was called Giustino. Gravina had it printed in 1713; but the play is lifeless; and forty-two years afterwards we find Metastasio writing to his publisher, Calabigi, that he would willingly suppress it. Caroprese died in 1714, leaving Gravina his heir; and in 1718 Gravina also died. Metastasio inherited house, plate, furniture and money, which amounted to 15,000 scudi, or about £4000. At a meeting of the Arcadian Academy, he recited an elegy on his patron, and then settled down, not it seems without real sorrow for his loss, to enjoy what was no inconsiderable fortune at that period. Metastasio was now twenty. During the last four years he had worn the costume of abbe, having taken the minor orders without which it was then useless to expect advancement in Rome. His romantic history, personal beauty, charming manners and distinguished talents made him fashionable. That before two years were out he had spent his money and increased his reputation for wit will surprise no one. He now very sensibly determined to quit a mode of life for which he was not born, and to apply himself seriously to the work of his profession. Accordingly he went to Naples, and entered the office of an eminent lawyer, Giovanni Caraceni. It would appear that he entitled himself as clerk for Castagnola exercised severe control over his time and energies. While slaiving at the law, Metastasio in 1721 composed an epitaphium, and probably also his first musical serenade, Endimione, on the occasion of the marriage of his patroness the Princess Pinelli di Sangro to the Marchese Belmonte Pignatelli. The event which fixed his destiny, was the following. In 1722 the birthday of the emperor had to be celebrated with more than ordinary honours, and the viceroy applied to Metastasio to compose a serenade for the occasion. He accepted this invitation, but it was arranged that his authorship should be kept secret. Under these conditions Metastasio produced Gli orfi espideri. Set to music by Porpora, it won the most extraordinary applause. The great Roman prima donna, Marcella Bucarelli, called La Romanina from her birthplace, who had played the part of Venus in this drama, spared no pains until she had discovered its author. La Romanina forthwith took possession of him, induced him to quit his
METASTASIO

lawyer's office, and promised to secure for him fame and independence, if he would devote his talents to the musical drama. In La Romanina's house Metastasio became acquainted with the greatest composers of the day—with Porpora, from whom he took lessons in music; with Hasse, Pergolesi, Scarlatti, Vinci, Leo, Durante, Marcello, all of whom were destined in the future to set his plays to melody. Here too he studied the art of singing, and learned to appreciate the style of such men as Farinelli. Gifted himself with extraordinary facility in composition, and with a true poetic feeling, he found no difficulty in producing plays which, while beautiful in themselves, judged merely as works of literary art, became masterpieces as soon as their words were set to music, and rendered by the singers of the greatest school of vocal art the world has ever seen. Reading Metastasio in the study, it is impossible to do him justice. But the conventionality of all his plots, the absurdities of many of his situations, the violence he does to history in the persons of some leading characters, his "damnable iteration" of the theme of love in all its phases, are explained and justified by music.

Metastasio resided with La Romanina and her husband in Rome. The generous woman, moved by an affection half maternal half romantic, and by a true artist's admiration for the rare talent, adopted him more passionately even than Gravina had done. She took the whole Trapassi family—father, mother, brother, sisters—into her own house. She fostered the poet's genius and pampered his caprices. Under her influence he wrote in rapid succession the Didone abbandonata, Catone in Utica, Enea, Alessandro nell'Indie, Semiramide riconosciuta, Siroe and Artaserse. These dramas were set to music by the chief composers of the day, and performed in the chief towns of Italy. But meanwhile La Romanina was growing older; she had ceased to sing in public; and the poet felt himself more and more dependent in an irksome sense upon her kindness. He gained 300 scudi (about £60) for each opera of this pay, though good-natured and sacrificial, he longed for some firmer engagement. In September 1720 he received the offer of the post of court poet to the theatre at Vienna, with a stipend of 3000 florins. This he at once accepted. La Romanina unsparingly spent him on his way to glory. She took the charge of his family in Rome, and he set off for Austria.

In the early summer of 1730 Metastasio settled at Vienna in the house of a Spanish Neapolitan, Niccolò Martinez, where he resided until his death. This date marks a new period in his artistic activity. Between the years 1730 and 1740 his finest dramas, Adriano, Demetrio, Issipile, Demofonte, Olimpia, Cleomeni di Tito, Achille in Sciro, Temistocle and Attilio Regolo, were produced for the Imperial theatre. Some of them had to be composed for special occasions, with almost incredible rapidity—the Achille in eighteen days, the Ipermestra in nine. Poet, composer, musical copyist and singer did their work together in frantic haste. Metastasio understood the technique of the peculiar art in its minutest details. The experience gained at Naples and Rome, quickened by the excitement of his new career at Vienna, enabled him almost instinctively, and as it were by inspiration, to hit the exact mark aimed at in the opera.

At Vienna Metastasio met with no marked social success. His plebeian birth excluded him from aristocratic circles. But, to make up in some measure for this comparative failure, he enjoyed the intimacy of a great lady, the Countess Althann, sister-in-law of his great patroness the Princess Belmonte Pignotti. She had lost her husband, and had some while occupied the post of chief favourite to the emperor. Metastasio's liaison with her became so close that it was even believed they had been privately married. The even tenor of his existence was broken in the year 1734 by the one dark and tragic incident of his life. It appears that La Romanina had at last got tired of his absence. "Could not (60) for each get her engagement at the court theatre? The poet at this juncture revealed his own essential feebleness of character. To La Romanina he owed almost everything as a man and as an artist. But he was ashamed of her and tired of her. He vowed she should not come to Vienna, and wrote dissuading her from the projected visit."

The tone of his letters alarmed and irritated her. It is probable that she set out from Rome, but died suddenly upon the road. All we know is that she left him her fortune after her husband's life interest in it had expired, and that Metastasio, overwhelmed with grief and remorse, immediately renounced the legacy. This disinterested act plunged the Bulgarelli-Metastasio household at Rome into confusion. La Romanina's widower married again. Leopoldo Trapassi, and his father and sister, were thrown upon their own resources.

As time advanced the life which Metastasio led at Vienna, together with the climate, told upon his health and spirits. From about the year 1745 onward he wrote but little, though the cantatas which belong to this period, and the canzonet Ecco quel fero estante, which he sent to his friend Farinelli, rank among the most popular of his productions. It was clear, as Vernon Lee has phrased it, that "what ailed him was mental and moral ennui." In 1755 the Countess Althann died, and Metastasio was consumed with the sincere regret which true friends round him in the bourgeois house of the Martinez. He sank rapidly into the habits of old age; and, though his life was prolonged till the year 1782, very little can be said about it. On the 12th of April he died, bequeathing his whole fortune of somewhat over 130,000 florins to the five children of his friend Martinez. He had survived all his Italian relatives.

During the long period of forty years in which Metastasio overlived his originality and creative powers his fame went on increasing. In his library he counted as many as forty editions of his own works. They had been translated into French, English, German, Spanish, even into modern Greek. They had been set to music over and over again by every composer of distinction, each opera receiving this honour in turn from several of the most illustrious men of Europe. They had been sung by the best virtuosi in every capital, and there was not a literary academy of note which had not conferred on him the honour of membership. "Strangers of distinction passing through Vienna made a point of paying their respects to the old poet at his lodgings in the Kohlmarkt Gasse. But his poetry was intended for a certain style of music—for the music of omnipotent vocalists, of thamaturgical sopranis. With the changes effected in the musical drama by Gluck and Mozart, with the development of orchestration and the rapid growth of the German manner, a new type of libretto came into request. Metastasio's plays fell into undeserved neglect, together with the music to which he had linked them. Farinelli, whom he styled "twin-brother," was the true exponent of his poetry; and, with the abolition of the class of singers to which Farinelli belonged, Metastasio's music suffered eclipse. It was indeed a just symbolic instinct which made the poet dub this unique soprano his twin-brother."

The musical drama for which Metastasio composed, and in working for which his genius found its proper sphere, has so weighed itself down with an awkwardness which is now difficult to bear, that the true poet of Metastasio's time to which the poet is linked is not the man of history. The chief dramatic situations are expressed by lyrics for two or three voices, embodying the several contending passions of the agents brought into conflict by the circumstances of the plot. The total result is not pure literature, but literature supremely fit for musical effect. Language in Metastasio's hands is exquisitely pure and limpid. Of the Italian poets, he professed a special admiration for Tasso and for Marini. But he avoided the conceits of the latter, and was no master over the refined richness of the former's diction. His own style reveals the improvvisatore's facility. Of the Latin poets he studied Ovid with the greatest pleasure, and from this predilection some of his own literary qualities may be derived. For sweetness of versification, for limpidity of diction, for delicacy of sentiment, for romantic situations exquisitely rendered in the simplest style, and for a certain delicate beauty of imagery sometimes soaring to ideal sublimity, he deserves to be appreciated so long as the Italian language lasts.

There are numerous editions of Metastasio's works. That by Casabari (Turin, 1755, 9 vol. 8vo) published under his own imprint, was the poet's favourite. Another of Turin (1757) and a...
third of Paris (1780) deserve mention. The posthumous works were printed at Vienna, 1795. The collected editions of Genca (1802) and Padua (1811) will probably be found most useful by the general student. An edition of the letters, by Cardacci, was published at Bologna 1811. Metastasio's life was written by Aluigi (Assisi, 1783); by Charles Burney (London, 1796); and by others; but by far the most vivid sketch of his biography will be found in Vernon Lee's Studies of the 18th Century in Italy (London, 1880) a work which was a floor of light in the development of his dramatic music, and upon the place occupied by Metastasio in the artistic movement of the last century.

* MÉTÀURUS (mod. Metauro; the form Metatars is later, and is more frequent in inscriptions of the imperial period), a river of Italy, which flows into the sea a little south-east of Fanum Fortunae (mod. Fano). On its banks Hasdrubal, while marching to the aid of Hannibal in 207 B.C., was defeated and slain by the Roman army, this being the decisive battle of the Second Punic War. The exact site of the battle is uncertain; tradition places it between Possembrone and the Furlo Pass, but it is probable that it occurred near the sea-coast.

METAXAS, ANDREAS (1786-1860), Greek politician, was born in the island of Cephalonia. During the latter part of the War of Independence (1824-1827) he accompanied Capo d'Istria to Greece, and was appointed by him minister of war. When Capo d'Istria was murdered in 1831 Metaxas became a member of the provisional government which held office till the accession of King Otho in 1833. During the minority of Otho he was named privy councilor and minister at Madrid and Lisbon. In 1840 he was recalled and appointed minister of war. In 1843-1844 he was president of the council of ministers, and he subsequently held the post of ambassador at Constantinople from 1850 to 1854. He died at Athens on the 19th of September 1860.

MÉTAYAGE SYSTEM, the cultivation of land for a proprietor by one who receives a proportion of the produce. The system has never existed in England and has no English name, but in certain provinces of Italy and France it was once almost universal, and is still very common. It is also not unusual in Portugal, in Greece, and in the countries bordering on the Danube. In Italy and France, respectively, it is called messeria and métayage, or halving—the halving, that is, of the produce of the soil between landowner and landholder. These expressions are not, however, to be understood in a more precise sense than that in which we sometimes talk of a larger and a smaller half. They merely signify that the produce is divisible in certain definite proportions, which must obviously vary with the varying fertility of the soil and other circumstances, and which do in practice vary so much that the landlord's share is sometimes as much as two-thirds, and sometimes as little as one-third. Sometimes the landlord supplies all the stock, sometimes only part—the cattle and seed perhaps, while the farmer provides the implements; or perhaps only half the seed and half the cattle, the farmer finding the other halves—taxes too being paid wholly by one or the other, or jointly by both.

English writers were unanimous, until J. S. Mill adopted a different tone, in condemning the métayer system. They judged it by its appearance in France, where it has never worn a very attractive aspect. Under the ancien régime not only were all direct taxes paid by the métayer, the noble landowner being exempt, but these taxes, being assessed according to the visible produce of the soil, operated as penalties upon all endeavours to augment its productiveness. No wonder, then, if the métayer fancied that his interest lay less in exerting himself to augment the taxes than in dividing between himself and his landlord, than in studying how to defraud the latter part of his rightful share; nor if he has not yet got rid of habits so acquired, especially when it is considered that he still is destitute of the fixity of tenure without which métayage cannot prosper. French métayers, in Arthur Young's time, were "removable at pleasure, and obliged to conform in all things to the will of their landlords," and so in general they are still. Yet even in France, although métayage and extreme rural poverty usually coincide, there are provinces where the contrary is the fact, as it is also in Italy.

Indeed, to every tourist who has passed through the plains of Lombardy with his eyes open, the knowledge that métayage has for ages been there the prevailing form of tenure ought to suffice for the triumphant vindication of métayage in the abstract. An explanation of the contrasts presented by métayage in different regions is not far to seek. Métayage, in order to be in any measure worthy of commendation, must be a genuine partnership, one in which there is no sleeping partner, but in the affairs of which the landlord, as well as the tenant, takes an active part. Wherever this applies, the results of métayage appear to be as eminently satisfactory, as they are decidedly the reverse wherever the landlord holds himself aloof.

In France there is also a system termed métayage par groupes, which consists in letting a considerable farm, not to one métayer, but to an association of several, who work together for the general good, under the supervision either of the landlord himself, or of his bailiff. This arrangement gets over the difficulty of finding tenants possessed of capital enough for any but very small farms.

See further the section Agriculture in the articles France, Greece, Italy, &c.; and consult J. Cruveilhier, Etude sur le métayage (Paris, 1894).

METCALF, WILLARD LEROY (1858- ), American artist, was born at Lowell, Massachusetts, on the 1st of July 1858. He was a pupil of the Boston Normal Art School, of the Boston Art Museum School, and of the Académie Julien, Paris. After early figure-painting and illustration, he became prominent as a landscape painter. He was one of the "Ten American Painters" who in 1897 seceded from the Society of American Artists. For some years he was an instructor in the Woman's Art School, Cooper Union, New York, and in the Art Students' League, New York. In 1893 he became a member of the American Water Colour Society, New York.

METCALFE, CHARLES THEOPHILUS METCALFE, BARON (1785-1846), Indian and colonial administrator, was born at Calcutta on the 30th of January 1785; he was the second son of Thomas Theophilus Metcalfe, then a major in the Bengal army, who afterwards became a director of the East India Company, and was created a baronet in 1802. Having been educated at Eton, he in 1800 sailed for India as a writer in the service of the Company. After studying Oriental languages as a first student at Lord Wellesley's College of Fort William, he, at the age of nineteen, was appointed political assistant to General Lake, who was then conducting the final campaign of the Mahratta war against Halkar. In 1808 he was selected by Lord Minto for the responsible post of envoy to the court of Ranjit Singh at Lahore; he remained in that capacity for five years, during the independence of the Sikh states between the Sutlej and the Jumna. Four years afterwards he was made resident at Delhi, and in 1819 he received from Lord Hastings the appointment of secretary in the secret and political department. From 1820 to 1825 Sir Charles (who succeeded his brother in the baronetcy in 1822) was resident at the court of the nizam, and afterwards was summoned in an emergency to his former post at Delhi. In 1827 he obtained a seat in the supreme council, and in March 1835, after he had acted as the first governor of the proposed new presidency of Agra, he provisionally succeeded Lord William Bentinck in the governor-generalship. During his brief tenure of office (it lasted only for one year) he carried out several important measures, including that for the liberation of the press, which, while almost universally popular, complicated his relations with the directors at home to such an extent that he resigned the service of the Company in 1838. In the following year he was appointed by the Melbourne administration to the governorship of Jamaica, where the difficulties created by the recent passing of the Negro Emancipation Act had called for a high degree of tact and ability. Sir Charles Metcalf's success in this delicate position was very marked, but unfortunately his health compelled his resignation and return to England in 1842. Six months afterwards he was appointed by the Peel ministry to the governor-generalship of Canada, and his success in carrying out the policy of the home government was rewarded with a
pearege shortly after his return in 1845. He died at Malshanger, near Basingstoke, on the 5th of September 1846.

METELLUS, the name of a distinguished family of the Caecilian (plebeian) gens in ancient Rome. The following are the most important:

1. LUCIUS CAECILIUS METELLUS, general during the first Punic War. Consul in 251 B.C., he was sent to Sicily, and gained a decisive victory over Hasdrubal, who, trusting to his numerically superior forces and the alarm inspired by his elephants, ventured to attack him. Metellus's victory was in great measure due to a panic caused amongst the elephants by his clever manoeuvring. A number of these animals were sent in specially constructed rafts to adorn his triumph, and from this time the elephant frequently occurs as a device on the coins of the Metelli. In 241, when the temple of Vesta was destroyed by fire, Metellus succeeded in bringing out the Palladium unharmed, but lost his eyesight. As a reward, he was granted permission to ride to the senate-house in a carriage, a privilege hitherto unheard of. But the story of his blindness is doubtful, since it is hardly consistent with his appointment as dictator in 224 "for the purpose of holding the comitia," nor is any mention made of it in the extract [Pliny, *Nat. Hist.* vii. 43 (45)] from the funeral oration pronounced over him by his son.

2. QUINTUS CAECILIUS METELLUS, son of (1), became consul in 206 as a reward for his services at the Metaurus. In 205 he was dictator for holding the comitia; in 201 one of the commissioners for dividing the public land in Samnium and Apulia amongst the Roman veterans; in 186 he conducted an embassy to Macedonia, afterwards proceeding to Peloponnesus to investigate the quarrel between Sparta and the Achaeanis. He is the Metellus who caused the poet Naevius (q.v.) to be imprisoned and exiled for having attacked him on the stage.

3. LUCIUS CAECILIUS METELLUS, possibly son of (1), when the disastrous news of the battle of Cannae (216) reached Rome, proposed to a number of young nobles that they should leave Italy and offer their services to some foreign ruler, but they were prevented by the threats of the younger Scipio from carrying out their purpose. For this offence, when quaestor two years later, he was degraded by the censors from his tribe to the class of *aerarii.* Nevertheless, he was elected one of the tribunes for the following year, but his attempt to call the censors to account for their action proved unsuccessful in the face of the opposition of his colleague.

4. QUINTUS CAECILIUS METELLUS MACEDONICUS (d. 115 B.C.), praetor 148 B.C., defeated the usurper Andiscus (q.v.) in Macedonia and forced him to surrender. Under his superintendence the province was made a Roman province. In 146, he attacked the Achaeanis to avenge an insult offered to a Roman embassy at Corinth. He gained decided successes over them at Scarpheia and Chaeroneia, but was superseded by L. Mummius. On his return to Italy he received the honour of a triumph and the title of *Macedonicus.* Consul in 143, he reduced the Celtiberians in northern Spain to obedience. In 131, when censor with Q. Pompeius (they were the first two plebeian censors), he proposed that all citizens should be compelled to marry. He expelled a number of senators, one of whom, the tribune C. Atinianus Labo, proposed that he should be hurled from the Tarpeian rock; his life was only saved through the intervention of another tribune. He was an opponent of the Gracchi, although not averse from moderate reform. He was a strict disciplinarian, a good general, and a type of the ancient Roman both in public and private life. He erected a splendid colonnade in the Campus Martius, and two temples dedicated to Jupiter Stator and Juno.

5. QUINTUS CAECILIUS METELLUS NUMIDICUS, consul 109, and commander in the Jugurthine War. He defeated Jugurtha (q.v.) by the river Muthul, and after a difficult march through the desert took his stronghold, Thala. Marius, however, who had been intriguing for the command, accused Metellus of postponing the war, and received the consulsiphip for 107 with the province of Numidia. Metellus received a splendid triumph and the title of *Numidicus.* Saturninus, whom as a censor he tried to remove from the senate, passed in 100 an agrarian law, inserting a proviso that all senators should swear to it within five days. All complied but Metellus, who retired to Asia. After Saturninus was killed he returned, and died (probably in 91). He was a man of the highest integrity, a strict and efficient general, and one of the chief leaders of the aristocratic party. He was a man of education and learning, and Cicero speaks highly of him as an orator.

6. QUINTUS CAECILIUS METELLUS PICTUS, so called from his efforts to bring about the recall of his father Numidicus from exile. He was one of the commanders in the Social War, and defeated Q. Pompeadius Silo, the Maristian leader (88). Sulla, on his departure for Asia, gave him proconsular command over south Italy. When Marius returned to Italy and joined Cinna, the soldiers, who had no confidence in the consul Gaeus Octavius, wished Metellus to take command, but he refused. The soldiers deserted in large numbers, and considering it impossible to defend Rome, Metellus retired to Africa and afterwards to Liguria, resuming his former proconsular command on Sulla's return. In the war against Marius he gained several important successes, and after his victory over C. Norbanus at Faventia (82) he subdued the whole of upper Italy. Consul in 80 with Sulla, he went to Spain next year against Sertorius, who pressed him hard till the arrival of Pompey in 76. Next year Metellus defeated Sertorius's lieutenant Hirtuleius at Italia and Segovia, and joining Pompey rescued him from the consequences of a check at Sucro. From this time Sertorius grew weaker till his murder in 72. In 71 Metellus returned to Rome and triumphed. He became pontifex maximus, and died probably at the end of 64. He was an upright man, of moderate ability.

7. QUINTUS CAECILIUS METELLUS CELER, legate of Pompey in Asia 66 B.C., praetor 63. He was despatched to cut off the retreat of Catiline to the north by blocking the passes, and in 62 went into the province of Cisalpine Gaul with the title of proconsul, although he did not become consul till 60. A strong supporter of the optimates and an enemy of Pompey, he strenuously opposed the agrarian law brought forward by the tribune Lucius Flavius, to provide for Pompey's veterans, and stood firm even though imprisoned; the law had to be given up. He also tried, though fruitlessly, to obstruct Caesar's agrarian law in 59. He died suddenly in the same year—it was usually supposed from poison administered by his wife Clodia.

8. QUINTUS CAECILIUS METELLUS NEPOS, son of a, Metellus of the same name, so called because he was the grandson of (4). He was legate to Pompey in the war against the Mediterranean pirates (67), and took part in the Syrian campaign. In 63 he returned to Rome, to assist Pompey in carrying out his plans. He violently attacked Cicero, and refused to allow him to deliver the customary speech on laying down office as consul; he even threatened to impeach him for having executed Roman citizens (referring to the Catilinarian conspirators) without a trial. In 62 his proposal that Pompey should be summoned to Italy to restore order was bitterly opposed by Cato, and on the day set down for the bill a fight took place in the forum. Metellus fled to Pompey, but soon returned with him to Rome. In 60, when praetor, he proposed a law for the abolition of the *vectigalia* in Italy. In 57 he was consul, but offered no opposition to the return of Cicero from exile. In 56 he was governor of Hither Spain, where he was engaged in hostilities against the Vaccumii with indifferent success. He appears to have died in Rome in the following year. He was a mere creature of Pompey.

9. QUINTUS CAECILIUS METELLUS PICTUS SCIFO, son of P. Scipio Nasica, was adopted by (6); and was accused of bribery in 60 B.C., and defended by Cicero, to whom he had rendered valuable assistance during the Catilinarian conspiracy. In August 52, he became consul through the influence of Pompey, who had married his daughter Cornelia. In 49 he proposed that Caesar should disband his army within a definite time, under pain of being declared an enemy of the state. After the outbreak of the civil war, the province of Syria was assigned to
him, and he was about to plunder the temple of Artemis at Ephesus when he was recalled by Pompey. He commanded the centre at Pharsalus, and afterwards went to Africa, where by Cato's influence he received the command. In 46 he was defeated at Thapsus; while endeavouring to escape to Spain he fell into the hands of P. Sittius, and put himself to death. His connexion with two great families gave him importance, but he was selfish and licentious, wanting in personal courage, and his violence drove many from his party.

10. QUINTUS CAECILIUS METELLUS, surnamed Creticus, Roman general. Consul in 69 B.C., he was appointed to the command of the war against Crete, the headquarters of the pirates of the Mediterranean. Its subjugation proceeded slowly but surely until 67, when Pompey claimed the control of affairs in virtue of the powers conferred upon him by the Gabinius law. Thereupon the Cretans, who had been treated with great harshness by Metellus, offered to surrender to Pompey, who enjoyed a reputation for leniency towards the conquered. Pompey accepted the offer and sent instructions to Metellus to suspend operations. Metellus refused and completed the conquest of the island, which was annexed to Cyrene and became a Roman province. Metellus's return to Rome the partisans of Pompey succeeded in keeping him out of the city until after the Catilinarian conspiracy, when he made his entry into the city and received the name Creticus in honour of his achievements. Metellus naturally joined the senatorial party in their opposition to Pompey, and had the satisfaction of preventing the ratification of what he had done in Asia. He was one of a commission of three sent (60) to investigate the state of affairs in Gaul, where disturbances were apprehended. He appears to have been alive in 54, but nothing further is known of him.

The family of the Metelli generally, see M. Wende, De Caecilia Metellis, i (Bonn, 1875), for its history up to the time of the Gracchi; the new edition by P. E. Münzer, Geschichte Romes, ii; and the article s.v. "Caecilien" by F. Münzer in Pauly-Wissowa's Realencyclopädie der klassischen Altertumswissenschaft, iii. pt. 1 (1897).

METEMPSYCHOSIS (Gr. μετεμψύχωσις), or TRANSMIGRATION OF THE SOUL, the doctrine that at death the soul passes into another living creature, man, animal, or even plant. This doctrine, famous in antiquity and still held as a religious tenet by certain sects of the civilized world, has its roots far back in primitive times. It is developed out of three universal savage beliefs: (1) that man has a soul, (2) that animals and even plants have souls, and are possessed to a large extent of human powers and passions; (3) that souls can be transferred from one organism to another. Innumerable examples might be mentioned of the notion that a new-born child is the reincarnation of someone departed, as in Tibet the soul of the Dalai-Lama is supposed to pass into an infant born nine months after his decease. Transmigration of human souls into non-human bodies is implied in totemism (q.v.), for, as Professor Frazer says, "it is an article of faith that as the clan sprang from the totem, so each clansman at death reassumes the totem form." All these savage notions are to be regarded as presuppositions of metempsychosis, rather than identified with that doctrine itself as a reasoned theory.

Till full investigation of Egyptian records put us in possession of the facts, it was supposed that the Egyptians believed in metempsychosis, and Herodotus (ii. 123) explicitly credits them with it. He now knows that he was wrong. All that they believed was that certain privileged souls might in the other world be able to assume certain forms at pleasure, those of a sparrow-hawk, lizard, &c. Herodotus misunderstood the Egyptians to hold beliefs identical with those which were current in his day in Greece. In India, on the contrary, the doctrine was thoroughly established from ancient times; not from the most ancient, as it is not in the Vedas; but onwards from the Upanishads. In them it is used for moral retribution: he who kills a Brahman is, after a long progress through dreadful hells, to be reborn as a dog, pig, ass, camel, &c. This we always find in metempsychosis as a reasoned theory. It is formed by combination of two sets of ideas which belong to different planes of culture: the ideas of judgment and punishment after death elaborated in a relatively cultured society by a priestly class are combined with ideas, like that of totem-transmigration, proper to a savage society. In India we may explain the whole phenomenon as an infusion of the lower beliefs of the non-Aryan conquered races into the higher religious system of their Aryan conquerors. In later Hinduism metempsychosis reached a monstrous development; according to Monier-Williams it was believed that there were 8,400,000 forms of existence through which all souls were liable to pass before returning to their source in the Deity. Buddhism appeared as a reaction against this, and sought by a subtle modification to harmonize the theory with its own pessimistic view of the world. According to Buddhism there is no soul, and consequently no metempsychosis in the strict sense. Something, however, is transmitted, i.e. Karmas (character), which passes from individual to individual, till in the perfectly righteous man the will to live is extinguished and that particular chain of lives is brought to an end.

We do not know exactly how the doctrine of metempsychosis arose in Greece; it cannot, as was once supposed, have been imported from Egypt and is not likely to have come from India. It is easier to assume that it had never been extinguished were utilized for religious and philosophic purposes. The Orphic religion, which held it, first appeared in Thrace upon the semi-barbarous north-eastern frontier. Orpheus, its legendary founder, is said to have taught that "soul and body are united by a compact unequally binding on each; the soul is divine, immortal and aspires to freedom, while the body holds it in fetters as a prisoner. Death dissolves this compact, but only to re-imprison the liberated soul after a short time: for the wheel of life regrows inexorably. Thus the soul continues its journey, alternating between a separate unrestrained existence and fresh reincarnation, round the wide circle of necessity, as the companion of many bodies of men and animals. To these unfortunate prisoners Orpheus proclaims the message of liberation, that they stand in need of the grace of redeeming gods and of Dionysus in particular, and calls them to turn to God by ascetic piety of life and self-purification: the purer their lives the higher will be their next reincarnation, until the soul has completed the spiritual ascent of destiny to live for ever as God from whom it comes." Such was the teaching of Orphism which appeared in Greece about the 6th century b.c., organized itself into private and public mysteries at Eleusis and elsewhere, and produced a copious literature.

The earliest Greek thinker with whom metempsychosis is connected is Pherecydes; but Pythagoras, who is said to have been his pupil, is its first famous philosophic exponent. Pythagoras probably neither invented the doctrine nor imported it from Egypt, but made his reputation by bringing Orphic doctrine from North-Eastern Hellas to Magna Graecia and by instituting societies for its diffusion.

The real weight and importance of metempsychosis is due to its adoption by Plato. Had he not embodied it in some of his greatest works it would be merely a matter of curious investigation for the anthropologist and student of folk-lore. In the eschatological myth which closes the Republic he tells the story how Er, the son of Armenus, miraculously returned to life on the twelfth day after death and recounted the secrets of the other world. After death, he said, he went with others to the place of judgment and saw the souls returning from heaven and from purgatory, each according to his transmigrating power. They then chose new lives, human and animal. "He saw the soul of Orpheus changing into a swan, Thamyris becoming a nightingale, musical birds choosing to be men, the soul of Atalanta choosing the honours of an athlete. Men were seen passing into animals and wild and tame animals changing into each other." After their choice the souls drank of Lethe and then shot away like stars to their birth. There are myths and theories to the same effect in other dialogues, the Phaedrus, Meno, Phaedo, Timaeus and Laws. In Plato's view the number of souls was fixed;
The various kinds of meteors are probably but different manifestations of similar objects. Perhaps the most important meteors are those which, after their bright careers and loud detonations, descend upon the earth's surface and can be submitted to close inspection and analysis (see Meteorites). The fireball or bolide (Gr. βολίς, a missile) comes next in order from its size and conspicuous effects. It may either be interspersed with many smaller meteors in a shower or may be isolated. The latter usually move more slowly and approach rather near to the earth. The ordinary shooting stars vary from the brilliancy of a first- to a sixth-magnitude star. They exhibit a great dissimilarity in paths, motions and colours. The smallest and most numerous class are the telescopic meteors invisible to the naked eye. They range from the 7th magnitude to the smallest object perceptible in large telescopes.

The altitudes at which these bodies are visibly presented to us differ in individual cases. More than a thousand observations in duplicate have been made of the paths of identical meteors seen from two stations many miles apart. These pairs of observations have shown a parallax from which the elevation of the objects above the earth, the lengths and directions of their courses, &c. could be computed. The average heights are from 80 to 40 m. A few, however, first appear when higher than 80 m. and some, usually slow-moving meteors, descend below 40 m. But altitudes beyond 100 m. and within 20 m. are rare:

30 of the November Leonids give a mean height of 84\(\frac{1}{2}\) to 571 m. 40 of the August Perseids 80 to 54 m.

When the duration of a meteor's course is known and the velocity its flight has been correctly estimated it is easy to compute the velocity in miles. The visible life of an ordinary shooting star is, however, comprised within one second, and it is only rarely that such short time intervals can be accurately taken. The real velocities derived from good observations are rarely, if ever, under 7 or 8 m. per second, or over 60 or 70 m. per second. In a few exceptional cases abnormal speed has been indicated on good evidence. The slower class of meteors overtaking the earth (like the Andromedids of November) have a velocity of about 8 or 10 m. per second, while the swifter class (meeting the earth like the Leonids of November) have a velocity of about 44 m. per second.

When the members of a shower are observed with special regard to their directions it is seen that they diverge from a common focus. The apparent scattering or diversity of the flights is merely an effect of perspective upon objects really traversing parallel lines. The centre upon which the observed paths converge is called the radiant point or, shortly, the radiant. On every night of the year there are a great number of these radiants in action, but the large majority represent very attenuated showers. In 1876 the number of radiants known was 850; but about 5000 have been determined up to the present time. There are all sorts of radiants, however: many of the positions being multiple observations of the same showers. Thus the August Perseids, the returns of which have been witnessed more frequently than those of any other meteoric stream have had their radiant point fixed on more than 250 occasions.

There appear to be moving and stationary radiances, contracted and diffused radiances, and long-enduring and brief radiances. The Perseids are visible from about the 11th of July to the 20th
of August, the radiant having a daily motion of about 3° R.A. to E.N.E. The Lyrids also vary in the position of their radiant, but the Orionids form a stationary position from about the 9th to the 24th of October. A large proportion of the ordinary feeble showers also appear to be stationary.

Solid bodies (chiefly stone or stone and iron) enter the atmosphere from without at all conceivable angles and at a velocity of about 26 m. per second, while the earth's orbital velocity is about 18 2/3 m. per second. In thus rapidly penetrating the air heat is generated, the meteor becomes incandescent, and the phenomena of the streak or train is produced. Before the object can pierce the dense lower strata of air its material is usually exhausted, but on rare occasions it withstands the fiery ordeal, and fragments of the original mass fall upon the earth.

Multitudes of meteors infest space. On a clear moonless night one person may count eight or ten shooting stars in an hour. But there are more than twice as many visible in the early morning hours as in the evening, and during the last half of the year there are also more than twice as many as visible as during the first half. It is computed that twenty millions of meteors enter the atmosphere every day and would be visible to unassisted vision in the absence of sunlight, moonlight and clouds, while if telescopic meteors are included the number will be increased twentyfold. Ordinary meteors, in the region of the earth's orbit, appear to be separated by intervals of about 250 m. In special showers, however, they are much closer. In the rich display of the 12th of November 1833, the average distance of the particles was computed as about 15 m., in that of the 27th of November 1855 as about 20 m., and in that of the 27th of November 1872 as about 35 m.

The meteors, whatever their dimensions, must have motions around the sun in obedience to the law of gravitation in the same manner as planets and comets—that is, in conic sections of which the sun is always at one focus. The great variety in the apparent motions of meteors proves that they are not directed from the plane of the ecliptic; hence their orbits are not like the orbits of planets and short-period comets, which are little inclined, but like the orbits of parabolic comets, which often have great inclinations.

Historical records supply the following dates of abundant meteoric displays:

These showers occurred at intervals of about one-third of a century, while the day moved along the calendar at the rate of one month in a thousand years. The change of style is, however, responsible for a part of the alteration in date. The explanation of the meteor showers in terms of the elliptical orbits of meteoroids revolving around the sun in a period of 333 years, and that one portion of the elliptical orbit intersects that of the earth. As the meteors have been numerously visible in five or six successive years it follows they must be pretty densely distributed along a considerable arc of their orbit. It also follows that, as some of the meteors are seen annually, they must be scattered around the whole orbit. Travelling at the rate of 26 m. per second, they encounter the earth moving 18 2/3 m. per second in an opposite direction, so that the apparent velocity of the meteors is about 44 m. per second. They radiate from a point within the Sickle of Leo and are termed Leonids. In 1867 the remarkable discovery was made that Tempel's comet (1866 : 1) revolved in an orbit identical with that of the Leonids. That the comet and meteors have a close physical association seems certain. The disintegrated and widely dispersed material of the comet forms the meteors which embellish our skies on mid-November nights.

Fine meteoric showers occurred in 1798 (Dec. 7), 1838 (Dec. 7), 1872 (Nov. 27), 1885 (Nov. 27), 1892 (Nov. 23) and 1899 (Nov. 23 and 24), and the dates indicate an average period of 6-7 years for fifteen returns. The meteors move very slowly, as they have to overtake the earth, and their apparent velocity is only about 0. m. per second. They are directed from a point in the sky near the star γ Andromedae. Biela's comet of 1826, which had a period of 6-7 years, presented a significant resemblance of orbit with that of the meteors, but the comet has not been seen since 1852 and has probably been resolved into the meteoric stream of Andromedids.

Rich annual displays of meteors have often been remarked on about the 10th of August, directed from Perseus, but they do not appear to have exhibited periodical maxima of great strength. They are probably dispersed pretty evenly along a very extended ellipse agreeing closely in its elements with comet 1862 : III. But the times of revolution are doubtful; the probable period of the comet is 121 years and that of the meteors 105 years. This shower of Perseids is notable for its long duration in the months of July and August and for its moving radiant.

There was a brilliant exhibition of meteors on the 20th of April 1803, and in other years meteors have been very abundant on about the 10th to the 21st of April, shooting from a radiant a few degrees south-west of a Lyrae. The display is apparently an annual phenomenon, though with considerable differences in intensity, and the cycle of its more abundant returns has not yet been determined. A comet which appeared in 1861 had a very suggestive agreement of orbit when compared with that of the meteors, and the period computed for it was 415 years.

Apart from the instances alluded to there seem few coincidences between the orbital elements of comets and meteors. Halley's comet conforms very well, however, with a meteoric shower directed from Aquarius early in May. But there are really few comets which pass sufficiently near the earth to give rise to a meteoric shower. Of 80 comets seen during the 20 years ending 1863, Professor Herschel found that only two, viz. Demen's comet of 1881 and Finlay's of 1886, approached comparatively near to the earth's path, the former within 3,000,000 m. and the latter within 6,000,000 m.

Radiants of Principal Showers.—The following is a list of the chief radiant points visible during the year:

Many meteors exhibit the green line of magnesium as a principal constituent. Professor N. von Konkoly remarked in the fireball of 1873 (July 26) the lines of magnesium and sodium. Other lines in the red and green have been detected and found by comparison with the lines of marsh gas. Bright meteors often emit the bluish-white light suggestive of burning magnesium. In addition to magnesium and sodium the lines of potassium, lithium and also the carbon fluorides exhibited in cometary spectra, have been seen.

Meteoric observation has depended upon rough and hurried eye estimates in past years, but the importance of attaining greater accuracy by means of photography has been recognized. At several American observatories, and at Vienna, fairly successful attempts were made in November 1898 to photograph a sufficient number of meteor-trails to derive the Leonid radiant, and the mean position was at R.A. 15° 33' Dec. +2° 17'. But the materials obtained were few, the shower having proved inconspicuous. The photographic method appears to have practically failed during recent years, since there has
METEORA—METEORITE

been no brilliant display upon which to test its capacity. Really large meteors can be satisfactorily photographed, but small leaves no impression on the plates.

Meteors look larger than they are, from the glare and flaming effect due to their momentary combustion. The finer meteors on entering the air only weigh a few hundred or, at most, a few thousand pounds, while the smallest shooting stars visible to the eye may probably be equal in size to coarse grains of sand, and still be large enough to evolve all the light presented by them. (W. F. D.)

METEORA, a group of monasteries in Thessaly, in the northern side of the Peneus valley, not quite 20 m. N.E. of Trikkala, and near the village of Kalabaka (the ancient Aeginium, medieval Stagus or Stagoi). From the Cambunian chain two masses of rock are thrust southward into the plain, surrounded by isolated columns from 85 to 300 ft. high, "some like gigantic tusks, some like sugar-loaves, and some like vast stalagmites," but all consisting of iron-gone or reddish-brown conglomerate of gneiss, mica-slate, syenite and greenstone. The monasteries stand on the summit of these pinnacles; they are accessible only by aid of rope and net worked by a windlass from the top, or by a series of almost perpendicular ladders climbing the cliff. In the case of St Stephen's, the peak on which it is built does not rise higher than the ground behind, from which it is separated by a deep, narrow chasm, spanned by a drawbridge. Owing to the confined area, the buildings are closely packed together; but each monastery contains beside the monks' cells and water-cisterns, at least one church and a refectory, and some also a library. At one time they were fourteen in number, but now not more than four (the Great Monastery, Holy Trinity, St Barabam's and St Stephen's) are inhabited by more than two or three monks. The present church of the Great Monastery was erected, according to Leake's reading of the local inscription, in 1383 (Börnstad, the Swedish traveller, gives 1514), and is one of the largest and handsomest in Greece. A number of the manuscripts from these monasteries have now been brought to the National Library at Athens. Aeginium is described by Livy as a strong place, and is frequently mentioned during the Roman wars; and Stagos appears from time to time in Byzantine writers.

See W. M. Leake, Northern Greece (4 vols., London, 1835); Professor Krieg in Zetitschr. f. allg. Erdk. (Berlin, 1858); H. F. Tozer, Researches in the Highlands of Turkey (1861); L. Heuzey and H. Daumet, Mém. de l'archéologie de Macédoine (Paris, 1878), where there is a map of the monasteries and their surroundings; Guide-Joanne; Grice, vol. ii. (Paris, 1891).

METEORITE, a mass of mineral matter which has reached the earth's surface from outer space. Observation teaches that the fall of a meteorite is often preceded by the flight of a fireball (see METEOR) through the sky, and by one or more loud detonations. It was inferred by Chladni (1794) that the fireball and the detonations result from the quick passage of the meteorite through the earth's atmosphere.

The fall of stones from the sky, though not credited by scientific men till the end of the 18th century, had been again and again placed on record. One of the most famous meteorites fell in Phrygia and was worshipped there for many generations under the name of Cybele, the mother of the gods. After an oracle had declared that possession of the stone would secure to the Romans a continual increase of prosperity, it was demanded by them from King Attalus about the year 204 B.C., and taken with great ceremony to Rome. It is described by the historian as "a black stone, in the figure of a cone, circular below and ending in an apex above." Plutarch relates the fall of a stone in Thrace about 470 B.C., during the time of Pindar, and according to Pliny the stone was still preserved in his day, 500 years afterwards. Both Diana of the Ephesians "which fell down from Jupiter," and the image of Venus at Cyprus, appear to have been conical or pyramidal stones. One of the holiest reliques of Moslems is preserved at Mecca, built into a corner of the Kaaba; its history goes back far beyond the 7th century; the description of it given to Dr Partsch suggests that the stone had fallen from the sky. The oldest existing meteorite of which

Meteoritic falls are independent of thunderstorms and all other terrestrial circumstances; they occur at all hours of the day and night, and at all seasons of the year; they favour no particular latitudes. The number of stones which reach the ground from one fireball is very variable. In each of the two Yorkshire falls only one stone was found; the Guernsey County meteor yielded 30; at Toulouse, as many as 350 are estimated to have fallen; at Hesse, over 500; at Knyahinya, more than 1000; at L'Aigle, from 1000 to 2000; at both Pullusk and Mocs no fewer than 100,000 are estimated to have reached the earth's surface. The largest single mass seen to fall is one of those which came down at Knyahinya, Hungary, in 1866, and weighed 547 lb; but far larger masses, inferred from their characters to be meteorites, have been met with. The larger of the Cranbourne masses, now in the British Museum (Natural History), before rusting weighed 3½ tons; the largest of the masses brought by Lieut. Peary from western Greenland weighs 561 tons. A mass found at Bacubirito in Mexico is 13 ft. long, 6 ft. wide and 5 ft. thick, and is estimated to weigh 50 tons.

From observations of the path and time of flight of the luminous meteor it is calculated that meteorites enter the earth's atmosphere with absolute velocities ranging from 10 to 45 m. a second; but the speed of a meteorite after the whole of the resisting atmosphere has been traversed is extremely small and comparable with that of an ordinary falling body. According to Professor A. S. Herschel's experiments, the meteorite which fell at Middlesbrough must have struck the ground with a velocity of only 412 ft. a second. In the case of the Hesse fall, several stones fell on the ice, which was only a few inches thick, and rebounded without breaking the ice or being broken themselves. The depth to which a meteorite penetrates depends on the speed, form, weight and density of the meteorite and on the nature of the ground. At Stannen a meteoric stone weighing 2 lb entered to a depth of only 4 in.; the large Knyahinya stone already mentioned made a hole 11 ft. deep.

The area of the earth's surface occupied by towns and villages being comparatively small, the probability of a shower of stones falling within a town is extremely minute; the likelihood of a living creature being struck is still more remote. The first Yorkshire stone, that of Wold Cottage, struck the ground only 10 yds. from a labourer; the second, that of Middlesbrough, fell on the railroad only 40 yds. away from some platelayers at...
work; a stone completely buried itself in the highway at Kaba; one fell between two carters on the road at Charsonville, throwing the ground up to a height of 6 ft.; the Toussaint-Grois meteorite broke the pavement and was broken itself; the Křižlenovík stone fell within a few paces of a little girl; the Angers stone fell close to a lady standing in her garden; the Brauneau mass went through the roof of a cottage; at Macão, in Brazil, where there was a shower of stones, some oxen are said to have been killed; at Nadagolla, in India, a man was so near that he was stunned by the shock; while at Mhow, also in India, a man was killed in 1827 by a stone which is a true meteorite, and is represented by fragments in museum collections.

Though the surface of a meteoric stone becomes very hot during the early part of the flight through the air, it is cooled again during the latter and slower part of the flight. Meteorites are generally found to be warm to the touch if immediately dug out; at the moment of their impact they are not hot enough to char woody fibre on which they chance to fall, nor is the surface then soft, for terrestrial matter with which the surface comes into contact makes no impression upon the meteorite. Where many stones fall in one place, the ground is generally imaged out by a large area elongated in the direction of the flight of the luminous meteor, and the largest stones generally travel farthest. At Hessle, for instance, the stones were distributed over an area of 10 m. long and 3 m. broad.

Meteorites are almost invariably found to be completely covered with a thin crust such as would be caused by intense heating of the material for a short time; its thinness shows the slight depth to which the heat has had time to penetrate. They are presumably cold and invisible when they enter the earth's atmosphere, and become heated and visible during their passage through the air; doubtless the greater part of the superficial material flicks off as the result of the sudden heating and is left behind floating in the air as the trail of the meteor. The crust varies in aspect with the mineral composition of the meteorite; it is generally black; it is in most cases dull but is sometimes lustrous; more rarely it is dark-grey in colour. Each stone of a shower is in general completely covered with crust; but occasionally, as in the case of the Butsura fall, stones found some miles apart fit each other closely and the fitting surfaces are uncrusted, showing that a meteorite may break up during a late and cool stage of the flight through the atmosphere. A meteorite is generally covered with pittings which have been compared in size and form to thumbmarks; the pittings are probably caused by the unequal conductivity, fusibility and fragility of the superficial material. As picked up, complete and covered with crust, meteorites are always irregularly-shaped fragments, such as would be obtained on breaking up a rock presenting no regularity of structure.

About one-third, and those the most common, of the chemical elements at present recognized as constituents of the earth's crust have been met with in meteorites; no new chemical element has been discovered; the most frequent or plentiful in their occurrence are: aluminium, calcium, carbon, iron, magnesium, nickel, oxygen, phosphorus, silicon and sulphur; while less frequently or in smaller quantities are found antimony, arsenic, chlorine, chromium, cobalt, copper, hydrogen, lithium, manganese, nitrogen, potassium, sodium, strontium, tin, titanium, vanadium. The existence of minute traces of several other elements has been announced; of these special mention may be made of gallium, gold, iridium, lead, platinum and silver. Iron occurs chiefly in combination with nickel, and phosphorus almost always in combination with both nickel and iron (schreibersite); carbon occurs both as distinctively crystallized diamond and as graphitic carbon, the latter generally being amorphous, but occasionally having the forms of cubic crystals (cliftonite); free phosphorus has been found in one meteorite; free sulphur has also been observed, but may have resulted from the decomposition of a sulphide since the fall of the stone.

Of the mineral constituents of meteorites, the following are by many mineralogists regarded as still unrepresented among native terrestrial products: clinofenite, a cubic form of graphitic carbon; phosphorus; various alloys of nickel and iron; moissanite, silicide of carbon; cobaltite, carbon of iron and nickel (corresponding to cementite, carbide of iron, found in artificial iron); schreibersite, protosulphide of nickel; kamacite, sulphide of calcium: osbornite, oxy sulphide of calcium and titanium or zirconium; daubrèelite, sulphide of iron; magnesite, a species of silicate; mackinawite, a mass of metallic iron microscopically crystallized; it is in general very closely to those of terrestrial tridymite; mackeyite, according to one view, is the result of fusion of labradorite, according to another view, is an independent species chemically related to leucite; these and other compounds are present constitutively in the following terrestrial minerals: carbonitite, pine and forsterite; enstatite and bronzite; diopside and augite; anorthite, labradorite and oligoclase; magnetite and chromite; pyrites; pyrrhotite; breunnerite. Quartz (silica), the most common of terrestrial minerals, is absent from the meteoric iron; but from the Terra meteoric iron microscopically crystallized have been observed, which have given rise to quartz, and others to zircon. Free silica is present in the Breitenbach meteorite but as asanite. In addition to the above there are several combinations of minerals of which the nature has not yet been satisfactorily ascertained.

Meteorites are conveniently distributed into three classes, which pass more or less gradually into each other: the first (siderites or meteoric irons) includes all those which consist mainly of metallic iron alloyed with nickel; only nine of them have been actually seen to fall; the second (siderolites) includes all those in which metallic iron (alloyed with nickel) and stony matter are present in large proportion; few of them have been seen to fall; those of the third class (aerolites or meteoric stones) consist almost entirely of stony matter; nearly all have been seen to fall.

In the meteoric iron, the iron generally varies from 80 to 95% and the nickel from 6 to 10%; the latter is generally alloyed with the iron, and several alloys or mixtures have been distinguished by special names (kamacite, taenite, plessite). Trolite is frequently present as plates, veins or large nodules, sometimes in association with graphite, sometimes with pyrites, and occasionally also daubréelite. The composition and structure of meteoric iron are well shown by the figures generally called into existence when a polished surface is etched by means of acids or bromine-water; they are due to the inequality of the etching action on thick and thin plates of various constituents, the plates being composed chiefly of two nickel-iron materials (kamacite and taenite). A third nickel-iron material (plessite) fills up the spaces formed by the intersection of the joint plates of kamacite and taenite; it is probably not an independent substance but an intimate intergrowth of kamacite and taenite. The figures were first observed in 1808 and are generally termed "Widmanstätten figures" in honour of their discoverer; the plates which give rise to them are parallel to the faces of the regular octahedron, and such masses have therefore an octahedral structure. A small number of the above there are several compounds or mixtures; instead of Widmanstätten figures, they yield fine linear furrows when etched; the furrows were found by Neumann in 1848 to have directions such as would result from twinning of the cube about an octahedral face; they are known as "Neumann lines." For meteoric irons of cubic structure the percentage of nickel is lower than 6 or 7; for those of octahedral structure it is higher than 6 or 7; the plates of kamacite are thinner, and the structure therefore finer the higher the percentage of that metal. A considerable number of meteoric irons, however, show no crystalline structure at all, and have percentages of nickel both below and above 7; it has been suggested that each of these masses may once have had crystalline structure and that it has disappeared as a result of prolonged heating throughout the mass while the meteorite has been passing near a star.

An investigation of the changes of the magnetic permeability of the Sacramento meteoric iron with changing temperature led Dr S. W. J. Smith to infer that the magnetic behaviour can only be explained by imagining the meteorite to consist
METEOROLOGY

largely of plates of nickel-iron containing about 7% of nickel (kamacite), separated from each other by thin plates of a nickel-iron constituent (taenite), containing about 27% of nickel and having different thermomagnetic characters from those of kamacite; he suggests, however, that taenite is not a definite chemical compound but a eutectic mixture of kamacite and a nickel-iron compound containing not less than 53% of nickel.

About eleven out of every twelve of the known meteoric stones belong to a division to which Rose gave the name "chondritic" (χονδρίτης, a grain); they present a very fine-grained but crystalline matrix or paste, consisting of olivine and enstatite or bronzite, with more or less nickel-iron, trolite, chromite, augite and triclinic feldspar; through this paste are disseminated round chondrules of various sizes and generally with the same mineral composition as the matrix; in some cases the chondrules consist wholly or in great part of glass. Some meteorites consist almost solely of chondrules; others contain only few, in some cases the chondrules are easily separable from the surrounding material. In mineral composition chondritic meteorites approximate more or less to terrestrial lherzolites.

A few meteorites belonging to the chondritic division are remarkable as containing carbon in combination with hydrogen and oxygen; those of Alais and Cold Bokkeveld are good examples.

The remaining meteoric stones are without chondrules and contain little or no nickel-iron; of these the following may be mentioned as illustrative of the varieties of mineral composition: Juvinas, consisting essentially of anorthite and augite; Petersburg, of anorthite, augite and olivine, with a little chromite and nickel-iron (both Juvinas and Petersburg may be compared to terrestrial basalt); Sherbrooke, chiefly of augite and maskelynite; Askew, consisting wholly of augite, but olivine is present in small proportion; Bustee, of diopside, enstatite and a little triclinic feldspar, with some nickel-iron, olivahmite and osbornite; Bishopspule, of enstatite and triclinic feldspar, with occasional augite, nickel-iron, trolite and chromite; Roda, of olivine and bronzite; and Chassigny, consisting of olivine with enclosed chromite, and thus mineralogically identical with terrestrial dunite.

Almost all meteoric stones appear to be made up of irregular angular fragments, and some of them bear a close resemblance to volcanic tuffs. In the large group of chondritic stones, chondrules or spheres, some of which can only be seen under the microscope while others reach the size of a walnut, are embedded in a matrix apparently made up of minute splinters such as are formed by the disintegration of the chondrules themselves. In fact, until recently it was thought by some mineralogists that the chondrules owe their form, not to crystallization, but to friction, and that the matrix was actually produced by the wearing down of the chondrules through frequent collision with each other as oscillating components of a comet or during repeated ejection from a volcanic vent of some small celestial body. Chondrules have been observed, however, presenting forms and crystalline surfaces incompatible with such a mode of formation, and others have been described which exhibit features resulting from mutual interference during their growth. The chondritic structure is different from anything which has yet been observed in terrestrial rocks, and the chondrules are distinct in character from those observed in perlitic and obsidional.

It was generally believed that the structural features of meteoric stones are the result of hurried crystallization.

No organized matter has been found in meteorites and they have brought us, therefore, no evidence of the existence of living beings outside our own world.

AUTHORITIES.—The literature consists chiefly of memoirs dispersed through the journals of scientific societies. The following separate works may be consulted: A. Brezina, Die Meteoriten-Sammlung d. k.k. min. Hofkabinetts in Wien (Vienna, 1896); A. Brezina u. E. Cohen, Die Struktur und die Zusammensetzung der Meteoriten (Stuttgart, 1886-1887); P. S. Bigot de Morogues, Mémoire historique et physique sur les chutes des pierres (Orléans, 1812); Chladni, Über den Ursprung der von Pallas gefundenen und anderer Art abnormer Eisenmassen (Riga, 1794), and Über Feuer-Meteorite, und über die mit denselben herabgefallen Massen (Vienna, 1819); E. Cohen, Meteorienkunde (Stuttgart, 1894-1905); L. Fletcher, An Introduction to the Study of Meteorites, 10th ed. (London, 1908).

Rammeilberg, Die chemische Natur der Meteoriten (Berlin, 1870-1879); D. Rose, Beschreibung und Einheitlichkeit der Meteoriten (Berlin, 1880); L. Schurmann, Die meteorologische Beschaffenheit der Meteoriten (Stuttgart, 1883-1885); E. A. Wülfing, Die Meteoriten in Sammlungen und ihre Literatur (Tübingen, 1897).

METEOROLOGY (Gr. μετεωρός, and λέγος, i.e. the science of things in the air), the modern study of all the phenomena of the atmosphere of gasses, vapours and dust that surrounds the earth and extends to that unknown outer surface which marks the beginning of the so-called interstellar space. These phenomena may be studied either individually or collectively. The collective study has to do with statistics and general average conditions, sometimes called normal values, and is generally known as Climatology (see CLIMATE, where the whole subject of regional climatology is dealt with). The study of the individual items may be either descriptive, explanatory, physical or theoretical. Physical meteorology is again subdivided according as we consider either the changes that depend upon the motions of masses of air or those that depend upon the motions of the gaseous molecules; the former belong to hydrodynamics, and the latter are mostly comprised under thermodynamics, optics and electricity.

History.—The historical development of meteorology from the most ancient times is well presented by the quotations from classic authors compiled by Julius Ludwig Ideler (Meteorologis selenarum et manarum, Berlin, 1834). We owe to the Arabian philosophers some slight advance on the knowledge of the Greeks and Romans; especially as to the optical phenomena of the atmosphere. The Meteorologia of Aristotle (see Zeller, Phil. der Griechen) accords entirely with the Philosophies of Thomas Aquinas, the poetic songs of the troubadours, and the writings of Dante (see Kuhn's Treatment of Nature in Dante's Divine Comedy; London, 1807). Dante's work completed the passage from the ancient mythological treatment of nature to the more rational recognition of one creator and lawgiver that pervades modern science. The progress of meteorology has been coincident with the progress of physics and chemistry in general, as is shown by considering the works of Alhazen (1050) on twilight, Vitello (1250) on the rainbow, Galileo (1607) on the thermometer and on the laws of inertia, on attractions and on the weight of the air, Torricelli (1642) on the barometer, Boyle (1659) on the elastic pressure of air, Newton (1675) on optics; Cavendish (1766), elastic pressure of aqueous fluids (1753), separation of carbonic acid gas from ordinary air; Rutherford (1772), separation of nitrogen; Priestley and Scheele (1775) and Cavendish (1777), separation of oxygen; Lavositer (1785), general establishment of the character of the atmosphere as a simple mixture of gasses and vapour; De Saussure's measurement of relative humidity by the accurate hair hygrometer (1780), Dalton's measurement of vapour tension at various temperatures (1800), Regnault's and Magnus's revision of Dalton's tension of water vapor (1840), Marvin's and Juilins's measurements of tension of ice vapour (1851), and the isolation of argon by Rayleigh and Ramsay (1894).

Theoretical meteorology has been, and always must be, wholly dependent on our knowledge of thermodynamics and on mathematical methods of dealing with the forces that produce the motions within the atmosphere. Progress has been due to the most eminent mathematicians at the following approximate dates: Sir Isaac Newton (1670), Leonhard Euler (1736), Pierre Simon Laplace (1780), Jean Baptiste Joseph Fourier (1785), Simon Denis Poisson (1815), Sir George Gabriel Stokes (1851), Hermann von Helmholtz (1857), Lord Kelvin (1860), C. A. Bjerknes (1868), V. Bjerknes (1906), and to their many distinguished followers.

The earliest systematic daily record of local weather phenomena that has survived is that kept by William Merle, rector of Drify, during seven years 1331-1338: the manuscript is preserved in the Digby MS., Merton College, Oxford, and
was published in facsimile by George S. Symons in 1891. Doubtless many similar meteorastic diaries have been lost to us. In 1853, the Austrian II. of Tuscany organized a local system of stations and daily records which extended over and beyond northern Europe. This was the first fairly complete meteorological system in Europe. The records kept during the years 1655-1670 at the Cloister Angelus near Florence were reduced by Libri, professor of mathematics at Pisa, and published in 1830.

The history of meteorology is marked by the production of comprehensive treatises embodying the current state of our knowledge. Such were Louis Cotte's Traité de météorologie (Paris, 1774) and his Mémoires sur la météorologie, supplément au traité (1788); Ludwig Kätz's Lehrbuch der Meteorologie (Halle, 1831-1836) and his Vorzüge (1830; French 1842, English 1845); Sir John Herschel's Meteorology (London, 1840); the splendid series of memoirs by H. W. Brandes in Gehler's Physikalisches Wörterbuch (Leipzig, 1820-1840); E. E. F. W. Schmидt's Grundzüge der Meteorologie (Leipzig, 1862); Ferrel's Recent Advances in Meteorology (Washington, 1883); the great works of Julius Hann, as summarized in his Handbuch der Klimatologie (1883, 2nd ed., Stuttgart, 1897; vol. i. English 1903) and his Lehrbuch der Meteorologie (Leipzig, 1901, and ed. 1906); the extensive studies of J. E. Weiskoff (Veikof), as presented in his Klima der Erde (Russian 1883, German 1885) and his Meteorologie (Russian 1904).

The development of this science has been greatly stimulated by the regular publication of special periodicals such as the Zeitschrift of the Austrian Meteorological Society, 1866-1885, vol. 21 appearing with vol. 3 of the Meteorologische Zeitschrift of the German Meteorological Society in 1886, and since that date this journal has been jointly maintained by the two societies. The analogus journals of the Royal Meteorological Society, London, 1850 to date, the Scottish Meteorological Society, 1860 to date, the Meteorological Society of France, 1838 to date, the Italian Meteorological Society, and the American Meteorological Society, have all played important parts in the history of meteorology. On the other hand, the Annals of the Central Meteorological Office at Paris, the Archiv of the Deutsche Seewarte at Hamburg, the Annals and the Repertorium of the Central Physical Observatory at St Petersburg, the Annales of the Central Meteorological Office at Rome, Bulletin of International Simultaneous Met. Obs. and the Monthly Weather Review of the Weather Bureau at Washington, the Abhandlungen of the Royal Prussian Meteorological Institute at Berlin, the Meteorological Papers of the Meteorological Office, London, and the transactions of numerous scientific societies, have represented the important official contributions of the respective national governments to technical meteorology.

The recent international union for aerial exploration by kites and balloons has given rise to two important publications, i.e. the Veröffentlichungen of the International Commission for Scientific Aeronautics (Strasbourg, 1905, et seq.) and the records of observations, and the Beiträge zur Physik der freien Atmosphäre (Strasbourg, 1904, et seq.), devoted to research.

The necessity of studying the atmosphere as a unit and of securing uniform accuracy in the observations has led to the formation of a permanent International Meteorological Committee (of which in 1900 the secretary was Professor Dr G. Hellmann of Berlin, and the president Dr W. N. Shaw of London). Under its directions conferences and general congresses have been held, beginning with that of 1872 at Leipzig. Its International Tables, Atlas of Clouds, Codes of Instructions, and Forms for Climatological Publications illustrate the activity and usefulness of this committee.

Modern meteorology has been developed along two lines of study, based respectively on maps of monthly and annual averages and on daily weather maps. The latter study seems to have been introduced by H. W. von Bezoit in 1815, It was continued about 1820, compiled maps for 1823 from the data collected in the Ephemerides mundi heimensis, and subsequently published maps of the European storms of 1820 and 1821. Simultaneously with Brandes we find William C. Redfield in New York compiling a chart of the hurricane of 1821, which was published in 1831, and was the first of many memoirs by him on hurricanes that completely established their rotary and progressive motion. Soon after this Piddington and Sir William Reid began their great works on the storms of the Orient. About 1823 James Pollard Espy, in Philadelphia, began the publication of his views as to the motive power of thunderstorms and tornadoes, and in 1842 was appointed "meteorologist to the U.S. government" and assigned to work in the office of the surgeon-general of the army, where he prepared daily weather maps that were published in his four successive "Reports." In 1848 the three American leaders united in letters to Professor Joseph Henry, secretary of the Smithsonian Institution, urging that the telegraph be used for collecting data for daily maps and weather predictions. Favourable action was taken in 1849, the Smithsonian maps began to be compiled about 1851 and were displayed in public from 1853 onwards. Meanwhile in England James Glashier, with the help of the daily press, carried out similar work, publishing his first map in 1851 as soon as daily weather maps of sufficient extent could be promptly prepared by the help of the telegraph. The destructive storm of the 14th of November 1854, in the Crimea gave U. J. J. Le Verrier, at Paris, an opportunity to propose the proper action, and his proposals were immediately adopted by the secretary of war, Marshal Vaillant. On the 17th of February 1855 the emperor ordered the director-general of government telegraph lines to co-operate completely with Le Verrier in the organization of a bureau of telegraphic meteorology. The international daily bulletin of the Paris Observatory began to be printed in regular form on the Ist of January 1858, and the daily map of isobars was added to the text in the autumn of 1863. The further development of this bulletin, the inclusion of British and ocean reports in 1861, the addition of special storm warnings in 1863, the publication of the Atlas des mouvements généraux covering the Atlantic in 1865, the study of local thunderstorms by Gabriel Marie-Davy, Sonnel, Furst, Perny, Fyfe, and the work of Fitzroy, Buys-Ballot, Buchan, Glashier and Thomson in Great Britain, parallel the analogous works of the American students of meteorology and form the beginnings of our modern dynamic meteorology.

The details of the historical development of this subject are well given by Hug Hildebrand-Hildebrandson and Léon Teisserenc de Bort in their joint work, Les Bases de la météorologie dynamique (Paris, 1898-1907). The technical material has been collected by Hann in his Lehrbuch. Many of the original memoirs have been reprinted under Brillouin's direction in Mémoires, in Cleveland Abbe's Mechanics of the Earth's Atmosphere (vol. i., 1891; vol. ii., 1900).

The publication of daily weather charts and forecasts is now carried on by all civilized nations. The list of government bureaux and their publications is given in Bartholomew's Atlas (vol. iii., London, 1899). Special establishments for the exploration of the upper atmospheric conditions are maintained at Paris, Berlin, Copenhagen, St Petersburg, Washington and Strassburg.

The general problems of climatology (1900) are best presented in the Handbook of Dr Julius Hann (2nd ed., Stuttgart, 1897). The general distribution of temperature, winds and pressure over the earth's surface was investigated by the London Royal Society of Edinburgh in 1868, and again greatly revised and improved in the volume of the Challenger reports devoted to meteorology. The most complete atlas of meteorology is Buchan and Heath's Atlas of Meteorology (Paris, 1891). Excessive works of a more special character have been published by the London Meteorological Office, and the Deutsche Seewarte for the Atlantic, Pacific and Indian Oceans. Daily charts of atmospheric conditions for the whole of the northern hemisphere were published by the U.S. Weather Bureau from 1875 to 1883 inclusive, with monthly charts, the latter were continued through 1889. The physical problems of meteorology were discussed in Ferrel's Recent Advances (1883), and Weiss in Weather (1891, Mathematical Aspects, 1884). This subject will be found in the author's collection known as The Mechanics of the Earth's Atmosphere; the memoirs by Helmholtz and Von Bezoit contained in this collection have been made the subject of a special treatise by Joseph Henry Peirce (1886) entitled Vents contiguës et nuages. A general summary of our knowledge of the mechanics and physics of the atmosphere is contained in the Report on the International Cloud Work, by F. H. Bigelow (Washington, 1900). The extensive Lehrbuch (Leipzig, 1901; and ed., 1906) by Dr Julius Hann is an authoritative work. The optical
phenomena of the atmosphere are well treated by E. Mascart in his *Tratat d'optique* (Paris, 1891–1898), and by J. M. Penter, *Meteorologische Optik* (1904–1907). Of minor treatises especially adapted to collegiate courses of study we may mention those by Braun (Berlin, 1858); F. S. Blake (Boston, 1853); Moser (Boston, 1858); B. Van Beeber (Stuttgart, 1890); A. Moore (London, 1893); T. Russell (New York, 1895). The brilliant volume by Svante Arrhenius, *Kosmiiche Physik* (Leipzig, 1900) contains a section by Professor S. Bjerknes, in which the new hydrodynamic methods of Bjerknes are developed.

### 1. Fundamental Physical Data

There can be no proper study of meteorology without a consideration of the various physical properties of the atmospheric gases and vapours, each of which plays an independent part, and yet also reacts upon its neighbours.

Atmospheric phenomena are due in great measure to the presence of water-vapour, carbonic acid gas (carbon dioxide), ammonia, argon, helium, with slight traces of free hydrogen and hydro-carbons. The proportions in which these gases are present are quite constant, except that the percentage of aqueous vapour is subject to large variations. In an atmosphere that is saturated at the temperature of 90° F., as may occur in such a climate as that of Calcutta, the water may be 2% of the whole weight of any given volume of air. When this aqueous vapour is entirely abstracted, the remaining dry gas is found to have a very uniform constitution in all regions and at all altitudes where examination has been carried out. In this so-called dry atmosphere the relative weights are about as follows: Oxygen, 23-16; nitrogen and argon, 76-77; carbonic acid, 0-04; ammonia and all other gases, less than 0-01 in the lower half of the atmosphere but probably in larger percentages at high altitudes. Of still greater rarity are the highly volatile gases, argon (q.v.), neon, krypton and helium (q.v.).

### Outer Limits

These exceedingly volatile components of the atmosphere are supposed to be held defensively by the earth by the attraction of gravity, but are continually diffusing through the atmosphere outwards into interstellar space, and possibly also from that region back into the atmosphere. There are doubtless other volatile gases filling interstellar space and occasionally entering into one or the other of the various planets as well as of the sun itself; possibly the hydrogen and hydro-carbons that escape from the earth into the outer atmosphere ascend to regions inaccessible to man and slowly diffuse into the outer space. The laws of diffusion show that for each gas there is an altitude at which as many molecules diffuse inwards as outwards in a unit of time. This condition defines the outer limit of each particular gaseous atmosphere, so that we must not imagine the atmosphere to be limited by the absolute limit of space to which it can extend. Several layers, so-called intermediate layers, have been distinguished by Professor F. T. Trowbridge. (see C. T. Trowbridge, *On Luminous Meteor Trains* and "On Movements of the Atmosphere at Very Great Heights," *Monthly Weather Review*, Sept. 1907.)

Such observations are supposed to show that there is an appreciable thickness of the earth's atmosphere, which contains a density of a millionth part of that which prevails at the earth's surface. Such matter is not a gas in the ordinary use of that term, but is a collection of particles moving individually of each other, which are removed from the earth's surface by the winds which we call radiant energy. According to Störmer this radiant energy is that of electrons from the sun, and their movements in the magnetic field surrounding the earth give rise to our auroral phenomena.

According to Professor E. W. Morley, of Cleveland, Ohio, the relative proportions of oxygen and nitrogen vary slightly at the surface of the earth according as the areas of high pressure and low pressure alternate above the same locality, so that the constituents of the air are not the same at all points on the globe. His work seems to show a possible variation of a small fraction of 1%, and he suggests that the air descending within the areas of high pressure is probably slightly poorer in oxygen. The proportion of carbonic acid gas varies slightly with the region to the wind, increasing in proportion to the amount of the shelter; it is greater over the land than over the sea, and it also slightly increases by night-time as compared with day, and in the summer and winter as compared with the spring and autumn months. During the years 1896–1898 Professor Svante Arrhenius in the *Amer. Geol. Jour.*, published memoirs in which they argued that a variation of several per cent. in the proportion of carbonic acid gas is quite consistent with the existence of the annual and vegetable life and may explain the variations in climate during geological periods. But the specific absorption of this gas for solar radiations is too small (C. G. Abbot, 1903) to support this argument. The question whether free ozone exists in the atmosphere is still debated, but there seems to be no satisfactory evidence of its presence, except possibly for a few minutes in the neighbourhood of, and immediately after, a discharge of electricity. Very little is known of the other principal gases up to a considerable altitude can be calculated with close approximation by assuming a quiescent atmosphere and the ordinary laws of diffusion and elastic pressure; on the other hand, actual observations show that the composition going on in the atmosphere changes these proportions and brings about a fairly uniform percentage of oxygen, nitrogen and carbonic acid gas up to a height of 10 m.

### Aquous Vapours

The distribution of aqeous vapour is controlled by temperature quite as much as by convection and has very little to do with diffusion; the law of its distribution in air has been well expressed by Hann by the simple formula: \( \log \varepsilon = -\log \varepsilon_0 - 66517 \) where \( h \) is the height expressed in metres and \( \varepsilon_0 \) are the vapour pressures at the upper station and sea-level respectively. Hann's formula applies especially to observations made on mountains, but J. Siring, *Wissenschaftliche Luftfahrt*, III. (Berlin, 1900) has deduced from balloon observations the following formula for the free air over Europe:

### Mass

According to a calculation published in the *U.S. Monthly Weather Review* for February 1899, the total mass of the atmosphere is 1.125,000,000 of the mass of the earth itself but, according to Professor R. S. Newcomb, this formula: \( 10^0 = 239 \times 10^0 \), celestial dynamics shows that there may possibly be a gaseous envelope whose weight is not felt at the earth's surface, since it is held in dynamic equilibrium above the atmosphere; the mass of this outer atmosphere cannot exceed \( 1/90 \)th of the mass of the earth, and is probably far less, if indeed it is at all appreciable.

### Conductivity

Dry air is a poor conductor of heat, its coefficient of conduction being expressed by the formula: \( 0-000 0568 \times 10^{-4} \times 1 \) where the temperature \( T \) is expressed in centigrade degrees. This term is stated as a fact that a plate of air 1 centimetre thick can conduct through its substance for every square centimetre of its area, in one second, the difference of temperature between two faces of the plate is 1°C. enough heat to warm 1 gram of water or 1 cubic centimetre of air 0.000 0568°C. or 0.000 1°C. the figure 0.1850°C. is the thermometric coefficient as distinguished from the first, or 0.000 0568°C. A cubic centimetre of air 0.000 0568°C. has the same weight as an atmosphere and gives what a great effect on the air itself its poor conductivity may have.

### Diaethanomaly

Dry air is extremely diathermanous or transparent, to the transmission of radiant heat. For the whole moist atmosphere the principal coefficient of transmission increases very rapidly as the wave lengths increase and the air becomes more humid. If we consider the wave lengths of radiant heat from the sun, we find that the transmission of radiation heat becomes shorter as the wave length increases, and if we consider the wave lengths of radiant heat from the earth, we find that the transmission of radiation heat becomes shorter as the wave length increases. If we consider the wave lengths of radiant heat from the sun, we find that the transmission of radiation heat becomes shorter as the wave length increases, and if we consider the wave lengths of radiant heat from the earth, we find that the transmission of radiation heat becomes shorter as the wave length increases.
is still further diminished. In general one half of the heat received from the sun by the illuminated terrestrial hemisphere is absorbed by the clearest atmosphere, leaving the other half to reach the surface of the ground, provided there be no intercepting clouds. The thermal conditions generally observed at the immediate surface of the globe during hazy and cloudy weather are therefore of minor importance in the mechanism of the whole atmosphere, as compared with the influence of the heat retained within its mass.

The transmission of solar radiation through the earth's atmosphere is the fundamental problem of meteorology, and has been the subject of many studies, beginning with J. H. Lambert and P. Bouguer. The pyrheliometer of C. S. M. Pouillet gave us our first idea of the thermal equivalence of solar radiation of our atmosphere or the so-called "solar constant," the value of which has been variously placed at from 2 to 4 calories per sq. cm. per minute. At present the weight of the argument is in favour of 2-1, with a fair presumption that both the intensity and the quality of the solar radiation as it strikes the upper layers of our atmosphere are slightly variable. It is also likely that this "constant" does not represent the sun proper, but the remaining energy after the sunbeam has sifted through masses of matter between the sun and our upper atmosphere, so that it may thus come to have appreciable variations.

The coefficients of absorption for specific wave-lengths were first determined by L. E. Jowet, of Johns Hopkins University, for numerous vapour lines in 1892 (see W. B. Bulletin, No. 16). In 1904 C. G. Abbot published a table based on bicolour work at Washington showing the coefficient of atmospheric transmission for solar rays passing through a unit mass of air—namely, from the zenith to the ground. He showed that this coefficient increased with the wave-length; hence any change in the quality of the solar radiation will affect the general coefficient of transmission. The following table gives his averages for the respective wave-lengths, as deduced from ten clear days in 1901-1902 and nine clear days in 1903:

Any variation in the nature that the atmosphere receives from the sun will have a corresponding influence on meteorological phenomena. Such variations were simultaneously announced in 1903 by Charles Dufour in Switzerland and H. H. Kimball in Washington (Monthly Weather Rev., May 1903); the latter was then conducting a series of observations with Angström's electric compensation pyrheliometer, and his conclusions have been confirmed by the work of L. Gorczyński of Prague (1901-1906) and C. G. Abbot at Washington. Kimball's pyrheliometric work on this subject is still being continued; but meanwhile Abbot and Fowle from their bolometric observations at the Smithsonian Astrophysical Observatory have deduced preliminary values of the observed total energy of the solar constant, for numerous dates when the sky was very clear, as follows (see Smithsonian Misc. Coll., xlv, 78 and xvii, 403, 1907):

If the relative accuracy of these figures is 1%, as estimated by Abbot, then they demonstrate irregular fluctuations of 5%. But different observers and localities vary so much that Abbot estimates the reliability of the mean value, 2-12, to be about 10%. The causes of these variations are of such general nature that they probably move slowly eastward from day to day, and as the variability is comparable with that of other atmospheric data, therefore conservative meteorologists at present confine their attention to the explanation of terms like "solar constant," "solar constant solar radiation." The large local changes of weather and climate are not due to changes in the sun, but to the mechanical and thermodynamic interactions of earth and ocean and atmosphere.

The absorption of solar radiation by the atmosphere is apparently explained by the laws of diffuse radiation, selective diffusion and fluorescence in accordance with which each atom and molecule and particle becomes a new centre for the diffusion in all directions of the energy represented by some specific wave-length. The specific influences of carbon dioxide and water vapour are less than those of the liquid particles (and of cloud and rain) and of the great mass of oxygen and nitrogen that make up the atmosphere.

Specific Heat.—The capacity of dry air for heat varies according as the heat increases the volume of the air expanding under constant pressure and the pressure is assumed to be constant. The specific heat of dry air is, therefore,

\[ \text{specific heat} = \frac{1}{2} \frac{\text{heat} + \text{work}}{\text{change in temperature}} \]

The specific heat of dry air and steam, is, and is given by the expression \( C_v = \frac{2}{3} (0.2375 + 0.4960) \) where \( x \) is the number of kilograms of steam associated with 1 kilogram of dry air. As does not exceed 0.030 (or 30 grams) the specific heat \( C_v \) may be taken up to 0.250. The latent heat of condensation of moisture is a matter of great importance in the formation of cloud and rain.

Radiating Power.—The radiating power of clean dry air is so small that it is the capacity of the gases, but rather the result of the speed and bolometer demonstrate its existence. The coefficient of radiation of the moisture diffused in the atmosphere is combined with that of the particles of dust and cloud, and is nearly equal to that of an equal surface of lamp-black. From the normal diurnal change in temperature at high and low stations, it should be possible to determine the general coefficient of atmospheric radiative energy for the average condition of the air in so far as this is not obscured by the influence of the ground. J. F. Kimball's experimental work contains a result in calories that may be expressed as follows: the total radiation in twenty-four hours of a unit mass of average dust and air towards the earth and atmosphere, for a temperature of 0°C. is 799 calories, for a temperature of 30°C. is 311 calories. This very small quantity was confirmed by the observations of Trabert, published in 1882, who found that 1 gram of air at 278°C absolute temperature radiates 0.1655 calories per minute toward a black surface at the absolute zero. The direct observations of C. C. Hutchins on dry dusty air, as published in 1890, gave a much larger value—evidently too large. Small changes in water, vapour and carbon dioxide affect the radiation greatly. The discussion of this subject is reported by Prof. E. D. F. W. of the Allegheny Observatory, and published as "Bulletin G" of the U.S. Weather Bureau, shows the character and amount of the radiation of several gases, and especially the details of the process going on under normal conditions of the atmosphere.

Density.—The absolute density or mass of a cubic centimetre of dry air at the standard pressure, 760 millimetres, and temperature 0°C., is 0.001 29359 grams; that of a cubic metre is 1.29359 kilograms; that of a cubic foot is 0.08714 avdp. A variation of this density with pressure, temperature, moisture and gravity are in the Smithsonian meteorological tables, and give rise to all the movements of the atmosphere; they, therefore, of fundamental importance to the dynamic theory.

Expansion.—The air expands with heat, and the expansion of aqueous vapour is so nearly the same as that of dry air that the same coefficient may be used for the complex atmosphere itself. The specific volume of water vapour under identical pressures by the formula \( V = V_0 (1 + 0.00003658 T) \) or Fahrenheit degrees \( V = V_0 (1 + 0.000037) \).

Elasticity.—The air is compressed in proportion to the pressure, and the pyrheliometric flame is not the absolute temperature of 273°C. plus the centigrade temperature \( p \) is the barometric pressure in millimetres and \( v \) the volume of a cubic centimetre of dry air; or the reciprocal of the density of the gas, the constant \( R = 29.272 \) for dry atmospheric air when the centimetre,
METEOROLOGY

PHYSICAL DATA

The gram, the second and the centigrade degrees are adopted as units of measure, and differs for each gas. For aqueous vapour in a gaseous state and not near the point of condensation R has the value 47-061. For ordinary air in which $x$ is the mass of the aqueous vapour, and $y$ is the mass of the dry air, the equation becomes $p = \frac{29-272 + 47-061 x}{T}$. This equation is sometimes called the equation of condition peculiar to the gaseous state. It may also be properly called the equation of a gaseous frictionless fluid, differing from the equation $p = \frac{29-272 + \gamma x}{T}$ that the elastic pressure $p$ depends upon the temperature and the volume. The mose exact equations given by Van der Waals, Clausius, Thiesen, are not needed by us for the pressures that occur in nature.

Diffusion.—In comparison with the convective actions of the winds, it may be said that it is difficult for aqueous vapour to diffuse in the air. In fact, the distribution of moisture is carried on primarily by horizontal convection, due to the vertical convection due to ascending and descending currents. Diffusion proper, however, comes into play in the first moments of the process of evaporation. The coefficient of diffusion for aqueous vapour from the air is $0-18$ according to Stefan, or $0-190$ according to Winkelnkemper; that is, to say, for a unit surface of $1$ sq. centimetre, and a unit vertical gradient of moisture pressure of one atmosphere per centimetre, as we pass inward from the free surface of the water, that the most important condition facilitating evaporation is the action of the wind.

Viscosity.—When the atmosphere is in motion each layer is a drag upon the adjacent one that moves a little faster than it does. This drag is the so-called molecular or internal friction or viscosity. The coefficient of viscosity in gases increases with the absolute temperature, and its value is given by an equation like the following: $\phi = \frac{29-272 + 47-061 \gamma}{T}$, which is the formula given by Earl Barus (Ann. Phys., 1889, xxxii.). This expression implies that for air whose temperature is the absolute zero there is no viscosity, but that at a temperature of $0^\circ C$, or $273^\circ$ on the absolute scale, the coefficient of viscosity is $0-0002$ on the roentgen scale. If we now consider the push or pull of a layer of air 1 centimetre square past another layer distant from it by 1 centimetre at a uniform rate of 1 centimetre per second.

Friction.—The general motions of the atmosphere are opposed by the viscosity of the air as a resisting force, but this is an exceedingly feeble resistance as compared with the obstacles encountered on the earth's surface and the inertia of the rising and falling masses of warm and cold air. The coefficient of friction used in the meteorology is deduced from the observations of the winds and results essentially not from viscosity, but from the resistances of all kinds to which the motion of the atmosphere is subjected. The greater part of the resistance is due to the friction of the ground and the friction of the moving air. The friction of the moving air is increased by the dampness and the velocity of the moving masses by their division into smaller masses which penetrate the quiet air in all directions. The loss of energy due to this process and the conversion of kinetic into potential energy is called the coefficient of friction, or, more properly, convective-resistance.

The coefficient of resistance for the free air was determined by Moore and Fiddian. For ordinary the follower surface into the atmosphere is $0-18$ according to Stefan, or $0-190$ according to Winkelnkemper; that is, to say, for a unit surface of $1$ sq. centimetre, and a unit vertical gradient of moisture pressure of one atmosphere per centimetre, as we pass inward from the free surface of the water, that the most important condition facilitating evaporation is the action of the wind.

Temperature at Sea-Level.—The temperature of the air at the surfaces of the earth and ocean and throughout the atmosphere is the fundamental element of dynamic meteorology. It is best exhibited by means of isotherms or lines of equal temperature. The isotherms of the ocean, at or near the surface, are very much more rapid than those of the atmosphere, and in the atmosphere are sufficiently well known for meteorological needs, and are utilized most discreetly in the elaborate discussion of the hypsometric formula published by Angst in 1889 in the memoirs of the Central Meteorological Bureau of Berlin.

Temperature at Upper Levels.—The vertical distribution of temperature and moisture in the free air must be studied in detail in order to understand the systems of convection which dominate the circulation that characterize the earth's atmosphere. Many observations on mountains and in balloons were made during the 19th century in order to ascertain the facts with regard to the decrease of temperature as we ascend in the atmosphere; but it is now generally admitted that this decrease is highly influenced by local influences due to the insufficient ventilation of the thermometers and the nearness of the ground and the balloon. Strenuous efforts are being directed to the elimination of these disturbing elements, and in the present volume the graph for the free air by means of delicate thermographs carried up to great heights by small free "sounding balloons," and to lesser heights by means of kites. Many international balloon ascents have been made since such observations was devised by Bierkens and and first used in the United States Weather Bureau " Bulletin F," from ...
were deduced the following tables, published in the *Monthly Weather Review:

In this table the second column gives the altitude of the ground at the reel on which the kite wire was wound. The third column shows the average gradient in degrees Fahrenheit per 1000 ft. between the reel at the respective stations and an uniform altitude 5280 ft. above sea-level. The fourth column the total reduction to be applied to the temperature at the reel in order to obtain the temperature at the 1 m. level above sea. These gradients and reductions are based upon observations made only during the six warm months from May to October 1898.

The kite-work at the Blue Hill Observatory has been published in the *Results of the Annual Annals of the Harvard College Observatory*, beginning with vol. xii. It has been discussed especially by H. H. Clifton with reference to special meteorological phenomena, such as areas of high and low pressure, fair and cloudy weather, and the winds and their velocities at different elevations, insolation, radiation, and, has served as a stimulus and model for European meteorologists. Kite-work has also been successfully prosecuted at Trappes, Hampshire, and Paris, and at the German meteorological station at Berlin, which has been established under the auspices of the Prussian Meteorological Office, during the years 1887-1889. The results of these observations have been published in three volumes of *Wissenschaftliche Luftschifffahrt* (Berlin, 1900). The work done at Tegel at the Royal Aeronautical Office in Berlin, during the first 196 months of the first period of the expedition, the 1st of October 1900 to April 1905, was published in three volumes of *Ergebnisse*.

It is evident that the average annual vertical gradient of temperature over Paris is between 4° and 6° C. per 1000 metres of ascent in the free air, agreeing closely with the value 5° C. per 1000 metres, which has come into extensive use since the year 1890, on the recommendation and authority of Hann, for the reduction of land observations to sea-level. The winter gradients are less than those for summer, possibly due to the influence of the advection into cloud and rain during the winter season in France; the same value may not result from observations in the United States, where the clouds and precipitation of winter do not so greatly exceed those of summer. The winter is therefore not necessarily representative of the general average of the northern hemisphere, but belongs to a coastal region in which the gradient is not the same as that observed in the United States. The gradients between 4° and 6° C. per 1000 metres may also be used for calculation of coastal winds from the sea over the cold east winds from the land. Therefore, the average gradients of temperature over Paris are between 4° and 6° C. per 1000 metres at an altitude of 5280 ft. above sea-level. The average temperature at the level of 5280 ft. above sea-level is about 3° F. lower than that at sea-level. The average temperature at an altitude of 10,000 ft. above sea-level is about 5° F. lower than that at sea-level. The average temperature at an altitude of 20,000 ft. above sea-level is about 10° F. lower than that at sea-level. The average temperature at an altitude of 30,000 ft. above sea-level is about 15° F. lower than that at sea-level. The average temperature at an altitude of 40,000 ft. above sea-level is about 20° F. lower than that at sea-level. The average temperature at an altitude of 50,000 ft. above sea-level is about 25° F. lower than that at sea-level.

The growth of this aerial work and the reliability of the results may be inferred from a statement of the number of new observations made each year: 1899; 1900; 1901; 1902; 1903; 1904; 1905; 1906; 1907; 1908; 1909; 1910; 1911; 1912; 1913; 1914; 1915; 1916; 1917; 1918; 1919; 1920; 1921; 1922; 1923; 1924; 1925; 1926; 1927; 1928; 1929; 1930; 1931. This large number, combined with the 581 voyages of Teisserenc de Bort at Trappes and many others made in England.
Holland and Russia, amounting in all to 2000, enabled Assmann to compute the monthly and annual means of temperature and wind velocity for each altitude; the German results are given in table on page 269.

The results of these numerous ascents, during these six years, have also been grouped into monthly means that have a reliability proportionate to the number of days on which observations were obtained at a given level, and we are now able to speak of the annual and even of the diurnal periodicity of temperature at different altitudes in the free air with considerable confidence.

Some of the most important conclusions to be drawn from the best recent work published by Hann either in special memoirs or in his Lehrbuch, from which we take the following table. The actual temperatures given in this table have only local importance, but the differences of the vertical gradients doubtless hold good over a large portion of Europe if not of the world.

The differences of temperature between any layer and those above it and below it, or the vertical gradients at each level go through annual periodical changes quite analogous to those derived from mountain observations; the most rapid falls of temperature, at the largest vertical gradients in the free air occur on the following dates over Europe:

The values above given as deduced from 141 high ascensions at Trappes show that between 11 and 12 km, there was no appreciable diminution of temperature, in other words, the air is warmer than could be expected and therefore has a higher potential temperature. This fact was first confirmed by the Berlin ascensions, and is now recognized as wellnigh universal. The altitude of the base of the west wind is about 12 km. in areas of high pressure and 10 km. in areas of low pressure. It is higher as we approach the tropics and above ordinary balloon work near the equator if indeed it exists there. At first this unexpected warmth was considered as possibly a matter of error in the meteorographs, but this idea is now abandoned. Assmann suggested that the altitude that is of the highest cirrus, from which Cleveland Abbe inferred that it had something to do with the absorption of the solar and terrestrial heat by dissolving cirrus. But the most plausible explanation is that published simultaneously in September 1908 by W. J. Humphreys of Washington, and Ernest Gold of London.

The daily diagrams in Das Wetter show that both the irregular and the periodic and the geographic variations of temperature in the upper strata are unexpectedly large, almost as large as at the earth's surface, so that the upper temperature of space that was formerly supposed to prevail in the upper air must be looked for, if at all, far above the level to which sounding balloons have as yet attained. It is evident that both horizontal and vertical convection currents of great importance really occur at these great altitudes. These upper currents cannot be due to any very local influence at the earth's surface, but only to the interchange of the air over the oceans and continents or between the polar and equatorial regions. They constitute the important feature of the so-called general circulation of the atmosphere, which we have hitherto mistakenly thought of, as confined to lower levels; their general direction is from west to east over all parts of the globe as far as yet known, showing that they are controlled by the rotation of the earth. It is likely that masses of air having special temperature conditions or clouds of vapour dust such as came from Krakatoa, may be carried in these high currents around the globe perhaps several times before being dissipated.

The average eastward movement of the west wind at 3 km. above Germany is 10.7 m. per sec. or 1° of longitude (at 45° latitude) in 424 minutes, or such as to describe the whole circumference of this small circle in 10.5 days. At the equator above the calm belt the velocity westward or the east wind as given by Krakatau volcanic-dust phenomena was 34.5 m per sec., on 30° of a great circle daily, or around the equator in 12.5 days, while its poleward movement was only 1° per day or 1.3 metre per second. The average motion of the storm centres moving westward in northern tropical and equatorial regions but eastward in the north temperate zone is at the rate of one circumference or a small circle at latitude 45° in 19 days. Observations of the cloud movements gave Professor Biglow the following results for the United States:

Evidently, therefore, the great west wind (that James H. Coffin deduced from his work on the winds of the northern hemisphere and that William Ferrel deduced from his theoretical studies) represents with its gentle movement poleward a factor of fundamental importance. We must consider all our meteorological phenomena except at the equator as existing beneath and controlled, if not
caused, by this general deep swift current of air that began as an ascending east wind above the calm equatorial air but speedily overéowed as west wind settling down to the sea-level in the temperate and polar regions as great areas of high pressure and dry clear cool weather containing air on its return passage to the equator. The upper air is thrown easily into great billows, and wherever it rises the warm equatorial wind flows in beneath it, but when it descends we have blizzards and dry clear weather. It is a covering for lower strata of air, it flows clear with descending currents and sometimes mixes with them at the surface of contact. It receives daily accessions from below and gives out corresponding accessions to the lower strata, by a process of overturning such as has been studied theoretically by Margules and Bigelow.

At the fifth conference of the International Committee on Scientific Aeronautics (Milan, October 1906) Rykatchev presented the results of kite-work during 1904 and 1905 at Pavlovsk, near St Petersburg, from which he selected the results for these two years given in table at foot of page 270.

Many inversions occur during January below 1000 metres. The decrease is more rapid in summer than in winter and in clear weather than in cloudy, but of course this observations did not extend above the upper level of the cumulus cloud layer. A general survey of the existing state of knowledge of the upper atmosphere is given in the Report of the British Association for 1910.

**Distributed of Aqueous Vapour** is best shown by lines of equal dew-point or vapour tension, though for some purposes lines of equal relative humidity are convenient. The dew-point lines are not usually shown on charts, partly because the lines of vapour pressure are approximately parallel to the lines of mean temperature of the air, and partly because the observations are of very unequal accuracy in different portions of the globe. In general we may consider any isotherm as nearly parallel to the dew-points, but lower a degree or two degrees lower than the temperature of the air. The distribution of moisture is quite irregular both in a horizontal and in a vertical direction. On charts of the world we may draw lines based on absolute observations for the equal dew-point and equal vapour pressures; but as regards the distribution of moisture in a vertical direction we are, in the absence of specific observations, generally forced to assume that the vapour pressure at any altitude is follows the average law first stated by one of the number of observations by Han and Han, and expressed by the logarithmic equation, \[ \log v = \log v_0 - \frac{h}{6170}, \] which is quite analogous to the elementary hydrometric formula, \[ \frac{\rho}{\rho_0} = \rho_0 h - 18400. \]

Therefore, in general, the ratio between the pressure of the vapour and the pressure of the atmosphere at any altitude is represented by the approximate formula, \[ \log \frac{\rho}{\rho_0} = \log v_0 - \frac{h}{10001}. \]

Of course these relations can only represent average or normal conditions, which may be departed from very widely at any moment; they, however, have been found to agree remarkably with all observations which have as yet been published. The average results are given in the following table, which is abbreviated from one published by Han, but with the addition of the work done by the U.S. Weather Bureau, as reduced by Dr Frankenstein in 1899. The vapour constituent of the atmosphere is not distributed according to the law of gaseous diffusion, but, like temperature and the relative humidity, is distributed on account of the varying vertical water pressure, which is regulated by the winds and currents, namely—convection.

**Diminution of the Relative Pressure Vapour with Altitude.**

The total amount of vapour in the atmosphere, according to Han’s formula, is between one-fourth and one-fifth of the amount required by Dalton’s hypothesis, as is illustrated by the following table taken from an article by Cleveland Abbe in the Smithsonian Report for 1888, p. 410—

**Total Vapour in a Vertical Column that is saturated at its base.**

A heavy rainfall results from the precipitation of only a small percentage of the water contained in the fresh supplies of air brought by the wind; if all moisture abstracted from the atmosphere it could only affect the barometer throughout the equatorial regions by 2-8/13-6 inches, or about two-tenths of an inch, while at the polar regions the diminution would be much less than one-tenth. Evidently, therefore, it does not look at all as if the fall of pressure in this experiment is to be considered as the simple result of the condensation of the vapour into rain. The barometric pressure over the earth’s surface is shown by the isobars, or lines of equal pressure at sea-level; it can also be expressed by a system of complex spherical harmonics. As the indications of the mercurial barometer must vary with the variation of apparent gravity, whereas those of the aneroid barometer do not, it has been agreed by international Meteorological Conventions that for scientific purposes all atmospheric pressures, when expressed as barometric readings, must be reduced to one standard value of gravity, namely, its value at sea-level and at 45° of latitude. In this locality its value is such as to give in one second an acceleration of 980-8 centimetres, or 32-2 English ft. per second. The effect of the variation of apparent gravity with latitude is therefore to make the barometric reading at sea-level read too high, between 45° and the equator, and too low, between 45° and the pole. The gravity-correction to be applied to any mercurial barometric-reading at sea-level, in order to get the atmospheric pressure in the first line of the table at foot of this page (see Wissenschaftliche Luftfahrt, Bd. III., and Hann, Lehrbuch, 1906, p. 169). The observations on mountains gave Han the pressures in the second line. Siring’s figures result from the use of Ansmann’s ventilated psychrometer and are therefore very reliable.
standard units, should be given on the edge of a meteorological chart, unless the isobars shown thereon already contain this correction. On such charts it will be perceived that the barometric pressure at sea-level is by no means uniform over the earth's surface, and daily weathers will in some degree vary with the pressure. The highest and lowest pressures being storm centres and the highest pressures areas of clear, cool, dry weather. But even the normal average charts show high pressures over the continents in the winter and low pressures over the oceans in the summer. These conditions change with the seasons of the year and the summer time; moreover, Schuff (Pogg. Ann., 1832) first demonstrated that the average pressure in the neighbourhood of the equator is slightly less than that of the tropic, and that there is a still more considerable change of pressure towards the poles. The exact statement of these variations of pressure with latitude was subsequently worked out very precisely by Perrel, and forms the basis of his explanation of the general circulation of the earth's atmosphere and its influence on the barometer. The series of curves which is obtained by plotting the pressure at different localities, and published by the Royal Society of Edinburgh in 1868, as well as Buchan's later and more perfect charts in the meteorology of the "Challenger" Expedition, Edinburgh, 1889, and in Bartholomew's "Atlas" of 1878 is derived from sea-level pressure charts. In this manner, the height of the barometer is principally upon the size of the continent. A part of this annual variation in pressure is undoubtedly introduced by the methods of reduction to sea-level; indeed, if the data of the lower stations are reduced to sea-level by any of the methods of reduction which have been suggested, the barometric changes which we find the barometric conditions quite reversed. These annual changes are intimately connected as cause and effect with the annual changes of temperature, moisture and wind; it is evident that these changes are not really a state of equilibrium, but may be made up of a series of changes, and there is a reaction going on between the wind and the barometric changes, the resistance and rotation of the earth's surface such that the true relation between these factors is complex but fundamental and peculiar to each individual machine. The vertical distribution of pressure as deduced from observation shows a rate of diminution with increasing altitude very closely not entirely accordant with the laws of static equilibrium, but still nearly so. It is significant in this connection that the terrestrial variations of pressure from this law of static equilibrium are sufficient to show that, if our atmosphere is really in a state of equilibrium, it must be a matter of dynamics and not of statics. The general average relation of the density of the air to the altitude and temperature, and the vertical nature of the atmospheric circulation, as shown in the accompanying diagram (fig. 1), which is taken from a memoir on the equations of motion by Joseph Cottier, published in the U.S. Monthly Weather Review for July 1879. The diminution in the summer season, the amount of the changes depending on the conditions, but not for the temporary conditions that continually occur, follows a logarithmic law, and can undoubtedly be extended upwards for the normal atmosphere only to a height of 20 or 30 m., owing to the increase of density as the level ascends. It is noticeable, however, that the upper portions of the atmosphere. This diagram is based on the assumption that the atmosphere is in a state of convective equilibrium such that the ascending and descending masses expand and contract by the same laws as the earth's surface. The energy required to warm up as they descend, nearly but not quite in accordance with the adiabatic law of the change of temperature in pure gases.

The departure of atmospheric temperatures from the strictly adiabatic state is unknown. During the summer of 1884, when the heat absorbed by and radiated from moist or dry air. In 1890, Abbe showed that a very moderate rate of radiation from the atmosphere suffices to explain the cooling of slowly descending mass by radiation, and thus the lowering of temperature from the earth and sun, or the balance between warming by absorption and cooling by radiation, is the basis of the arguments of W. F. Humphreys (Astrophysics, Jan. 1900), and E. Gold (Proc. Roy. Soc., p. 87, iii., 45 A.), explaining the existence of the "thermometer." The direct evaluation of this radiation and absorption has been attempted by many. The genuine law (g-p) is applied by Gold as closely representing nature, whereas the following (1) and (2) required are for the determination of the height corresponding to one-half of the barometric pressure at sea-level; (2) an isothermal layer must exist at the level where the absorption of solar radiation equals that of the terrestrial and atmospheric radiations. The terrestrial and atmospheric radiations being constants, temperature of the earth's surface to the adjacent layer of air.

Limit of the Atmosphere.—The limiting height of the atmosphere must be set at some known elevation above 20 m., where the temperature falls to absolute zero. But the uncertainty of the various hypotheses as to the physical properties of the upper atmosphere fords us to entertain any positive ideas on this subject at the present time. If we define the outer limit of the atmosphere as that point at which the diffusion of gases inwardly just balances the diffusion outwards, then this limit must be determined not by some mathematical formula, but by the properties of gases as low temperatures and pressures under conditions as yet uninvestigated by physicists.

Cloudiness.—It is evident that the clouds (i.e.) are formed from chemical reactions and by the condensation of invisible moisture therein to numerous minute particles of water, ice or snow. Notwithstanding their transparency, these individual clouds of ice or water crystals, when collected in large masses, disperse the solar rays by reflection to such an extent that direct light from the sun is unable to penetrate to the ground, and shadow and partial darkness result. In a general survey of the atmosphere the geographical distribution of the clouds is found to be one of the most important. When the solar heat falls upon the surface of the cloud, it is absorbed and reflected back, the one half of the energy penetrates to the ground and of the surface of the ground. The air in contact with it acquires a higher temperature and greater buoyancy, while the ground and air beneath it remain colder and denser. The average cloudiness over the globe is therefore intimately related to the density and circulation of the atmosphere; it was first charted in general terms by L. Teissereau de Bort of Paris, about 1866. The manifold observations of the Cleveland and Cincinnati stations, and the conclusions which have been drawn from them, are probably more important than any of the results in the study of the average cloudiness. Acting on this idea, in 1868 Abbe asked from all of his correspondents to carry out the observations daily, not less than once or twice a day, and the results have been published, and the results are published in the Bulletin of the International Simultaneous Meteorological Observations for the whole northern hemispheres during 1884. Abbe worked on the U.S. Eclipse Expedition to the West Coast of Africa in 1884-1890, which was devoted to the determination of the heights and motions of the clouds by the special instrument of the marine nephoscope. This instrument takes advantage of the property of clouds that they reflect the sky, it gives the navigator a means of determining the bearing of a storm centre at sea by studying the lower clouds, better than he can possibly do by the observation of the winds alone. The importance of cloudiness as a factor in weather has been brought out by the International Meteorological Committee, which arranged for a complete year of systematic cloud-work by national weather bureaus and individual observatories throughout the world from May 1890 to June 1891. In this connexion, H. H. Clayton of the Blue Hill Observatory published a very comprehensive report on cloud forms in 1906. The complete report by Professor F. H. Bigelow on the work done by the U.S. Weather Bureau forms part of the annual report for 1896 and constitutes a remarkable addition to our knowledge of the subject. Some preliminary account of this work was published in the American Journal of Science for December 1899.

Although all the international cloud-work of 1896-1897 has now passed, we still have the individual observations, as in the case of the International Polar Research Work of 1883, yet a comprehensive study of the results still remains to be made. Some of these have, however, been brought together in Mohn's study of the "Fram" and in Hau's Lehrbuch and in Bigelow's Report on Cloud-Work. The mean altitudes of cirrus and strato-cumulus clouds resulted as follows.
Sensitivity.—The thermometer indicates the temperature of the outside surface of its own bulb only when the whole mass of the instrument has a uniform temperature. Assuming that by appropriate convection we can keep the surface of the thermometer at the temperature of the air we may say that ordinarily this itself is perpetually changing both in rapid oscillations of several degrees and in diurnal periods of many degrees, while the thermometer, on account of its own mass or thermal inertia, always lags behind the temperature of the air. On the other hand, radiant heat passes easily through the air, strikes the thermometer, and raises its temperature quite independently of the influence of the air whose temperature we wish to measure. Therefore, the temperature indicated by the artificial bath or water whose temperature is either higher or lower than its own. This coefficient indicates the rate per minute at which the readings change when the temperature of the surface of the bulb is the same as the temperature of the air. The rate of change of which the thermometer itself undergoes when its own temperature is two degrees different from that of the air; consequently, the thermometer will lag behind the air temperature to that amount by the corresponding amount. Assuming that the air itself flows fast enough to keep the surface of the bulb at the air temperature. When the air temperature ceases to rise or fall, and begins to change at the same rate in the opposite direction, the thermometer will fall to record the minimum or maximum temperature by an appreciable error depending upon the rapidity of the change, and will follow the new temperature changes with the same lag. For example, in the case just quoted, if a rising temperature suddenly changes to a falling temperature, the error of the thermometer at the maximum temperature will be two degrees, and yet the thermometer may be absolutely correct as compared with the standard when it is allowed five or ten minutes time. True the actual means obtained to determine the temperature of the free air at any moment within $\phi^\circ$ of a degree Centigrade, owing to the sluggishness of all ordinary thermometers and the perpetual variations in the temperatures of the atmosphere.

Radiation.—When a thermometer bulb is immersed in a bath of liquid, all radiant heat is cut off, but when hung in the open air it is subject to a perpetual interchange of radiations between itself and all its surroundings; consequently its own temperature has only an indirect connexion with that of the air adjacent to it. One of the most difficult problems of meteorology is to expose a thermometer to cut off such radiations and get the true temperature of the atmosphere at a specific place. The following are a few of the many methods that have been adopted to secure this end: Melloni put the naked glass bulbs within open sheltering caps of perforated silver paper. Flaugeres used a porcelaneous bulb within a thick sheet of silver paper enclosing a thin layer of non-conducting substance, like cotton or wool. The influence of radiation upon a thermometer depends upon the radiating and absorbing properties of its own surface; one silvered surface of which is a fine silver plate, one of chalk powder does nearly as well; glass much more imperfectly; while a polished silver surface reflects with ease, but radiates and absorbs with the greatest difficulty. Fourier proposed to use two thermometers side by side, one of plain glass and the other of blackened glass; the difference of these would indicate the effect of radiation at any moment; but instead of plain glass he should have used polished silver. His method was quite independent of the temperature of the air, and in 1866 A. Parkinson published a method whereby the thermometers were placed within a very light shelter of oiled paper. In order to use this method successfully, both the black and the silvered thermometers should be whirled by side air, and both were then exposed to the cold of the atmosphere. Various forms of open lattice-work and louvre screens have been devised and used by Glaisier, Kupffer, Stevenson, Stowe, Dove, Renou, Joseph Henry and others, in all of which the wind is to blow, while the latter cut off the greater part of the direct sunshine and other obnoxious radiations by day, and also prevent obnoxious radiation from the thermometer by night. The Italian physiologist Malli first prepared a special instrument by which the temperature of the outside is by a small whirling machine, or by attaching it to a string and wind it up like a sling. When this whirling is done in a shady place excellent results are obtained. Renou and Craig placed the thermometer in a thin metallic enclosure or shelter, and whirled the latter. Wild established the thermometer...
in a fixed louvered shelter, but by means of a ventilating apparatus drew currents of fresh air from below into the shelter, where they circulated rapidly and passed out. In Germany, since 1885, Dr. Assmann has developed the apparatus known as the ventilated psychrometer, where the free air is conducted at a speed of 2 miles per hour through a double shelter of thin metallic tubing, and the air is drawn in rapidly by means of a small ventilating fan. In the observations made by Abbe on the cruise of the "Pensacola" to the West Coast of Africa, the double bulb thermometer was mounted on a revolving bed that was moved back and forth. The inside of the wet-bulb tube was kept wet, so that its surface, being cooled by evaporation, could not radiate injuriously to the thermometer. In the system of exposure adopted by the U.S. Weather Bureau the dry and wet bulb thermometer is kept in a shelter, which is placed on the top of a column of air, and the column is rotated by means of an electric motor. The shelter, which is about 3 ft. cube, and is placed far enough above the ground or building to ensure free exposure to the wind. In using the revolving and ventilating methods it is customary to wait for a steady reading after the time of starting, and, with the second reading at the end of the second minute, and so on until no appreciable changes are shown in the thermometer. Of course in perfectly calm weather these methods can only give the temperature of the air for the exact locality of the thermometer. On the other hand, when a strong wind is blowing the indicated temperature is an average that represents the long narrow stream of air that has blown past the thermometer during the few minutes that the bulb may obtain approximately the temperature of the air.

**Change of Zero.**—All thermometers having glass bulbs, especially those of cylindrical shape, are sensitive to changes of atmospheric pressure. If the temperature is high enough the pressure of the 30 in., or at sea-level, stands higher on the glass tube than if it has been determined under a lower pressure on a mountain top. Therefore delicate thermometers, when transported to great heights, or during a rapid diminution of pressure, will read too low and need a correction for pressure. The zero-point also changes with time and with the method of treatment that the bulb has received as to temperature. Owing to the slow adjustment of the molecules of the glass bulb to the state of stable equilibrium, their relations among themselves and with the external air, the bulb of the thermometer will forever be depressed below the zero of the thermometer itself, however the bulb is freshly heated. At this time the freezing-point is temporarily depressed to an amount nearly proportional to the heating. The normal method of treatment consists in first determining the zero-point, and then gradually raising the temperature of the bulb by heating, and allowing it to cool slowly until a steady series of changes; in the course of ten years its freezing-point may have risen by 2° or 3° F., and, moreover, it changes by fifty a tenth of a degree between summer and winter. The only way to take account of this source of error from meteorological work is to discard the mercurial thermometer altogether; but instead of adopting that course, the use is generally recommended of thermometers whose bulbs are made of a special glass, upon which the glass of the ordinary type is merely superimposed. Any argument as to secular changes in the temperature of the atmosphere is likely to be greatly weakened by the unknown influence of this source of error, as well as by changes in the methods of expressing the result of observation.

**Barometer**.—The barometer (g.v.) indicates the elastic pressure prevailing in gaseous or liquid at the surface of the mercury in the open tube or cistern, provided that the fluid at that point is in a state of quiet relative to the mercury.

Any motion of the air will have an influence upon the reading quite independently of the prevailing elastic pressure. The pressure within a mass of gas at any point is the summation of the effects due to the motions of the myriad molecules of the gas at that point; it is therefore a function of the number of molecules, and the sides of the enclosure, which in this case is the surface of the mercury in the cistern of the instrument. If the barometer moves with respect to the general mass of the gas there is a change in it, and therefore in its pressure. If the barometer is at rest, then its position, and therefore the pressure, is unaltered. If it is in the general mass of the free gas, and a barometer giving correctly the pressure of the air at rest within a room will give a different indication if the instrument or the air is set in rapid motion so that the motions of the free gas and the motions of the barometer with the air it will indicate the elastic pressure within the air.

When the wind blows against an obstacle the air pressure is increased slightly on the windward side and diminished on the leeward side. It is thus obvious that in determining the pressure within the free atmosphere there is a large and variable influence due to such considerations. The influence of a gale of wind is to raise the elastic pressure within a room whose window faces to the windward, but to lower the pressure if the window faces to the leeward. The influence of the draught up chimney, produced by the wind blowing over its summit, is to lower the pressure within the room. The maximum effect of the wind in raising the pressure is given by the formula, \( P - P_0 = 0.000 038 3 \times V^2 \), where the pressure is given in inches and the velocity in miles per hour. This amounts to about one-tenth of an inch in a 50-m. wind, and to nearly four-tenths in a 100-m. wind. The diminution by a leeward window or a draught up chimney is usually less than this amount. This point of the effect of the wind in causing changes of pressure does not belong to the free atmosphere but to the method of exposure of the barometer, and can be eliminated only by methods first described by Abbe in 1882: it is a very different matter from the general diminution of pressure that is produced by the wind over a rotating earth and by the strong terrestrial force within a vortex. The latter is an atmospheric phenomenon, independent of instruments and locality, which in hurricanes and tornadoes may amount to several inches of the mercurial column, but which is not observed in barometric records. The diminution of pressure during a hurricane evidence of the fact that the low pressure due to the hurricane and the special diminution due to the exposure of the barometer are combined together, so that when the calm has returned the local pressure reaches a higher level than at any other period. The international comparisons of barometers show that discrepancies exist between the best normals or standards, and that ordinary barometers must always be compared with such standards at the temperatures and at the times for which they were designed.

The wind is measured either by means of its pressure against any obstacle or by revolving apparatus that gives some idea of the velocity of its movement. The pressure is supposed to interest the engineer and navigator, but the velocity is the fundamental meteorological datum; in fact, the pressure of the wind varies with the nature of the obstacle, the method of exposure, the density of the air, and even the mass of rain carried along with it.

Pressure anemometers date from the pendulous tablet devised by Sir Christopher Wren about 1667, and such pressure plates continue to be used in an improved form by Russian observers.

Normal pressure plates are made at a few English and Continental stations. The windmill anemometers devised by Schober and Woltmann were modified by Combes and Cassella so as to make an exceedingly delicate instrument for laboratory use; another modification of Richard is extensively used in the U.S. Weather Bureau. In the early part of the 19th century Edgeworth devised and Robinson perfected a windmill system in which hemispherical cups revolved around a vertical axis, and these have come into general use in both Europe and America. Many others have been made of the exact ratio of the cups to the size of the wind, and the Robinson anemometer. The factor 3 is usually adopted and incorporated into the mechanism of the apparatus, but in ordinary circumstances this factor is entirely too large, and the recorded velocity is therefore too small. An apparatus was invented by A. F. Marvin deduced the table (see p. 275) for reduction from recorded to true velocity. This table involves the moment of inertia of the revolving parts of the instrument and the stiffness of the wind, and it will therefore, of course, not apply strictly to the types of instruments or winds, for which special studies must be made.

About 1842 a committee of the American Academy of Arts and Sciences experimentally determined, for a large variety of chimney and cistern anemometers of different kinds, the velocity of the wind necessary to cause a particular speed of rotation of the apparatus. This work was published by Robert Robinson in English and French, and the French version was translated into Russian by M. Caspelli, and improved by Combes and Cassella. The table was further improved by Sir Robert Robinson and others. A. F. Marvin deduced the table (see p. 275) for reduction from recorded to true velocity. This table involves the moment of inertia of the revolving parts of the instrument and the stiffness of the winds, and will therefore, of course, not apply strictly to the types of instruments or winds, for which special studies must be made.
within which barometric pressure is less than in the neighbouring free air. The draught up the chimney is due to the pressure of the air at the lower end of flame pushing up the fire into this region of low pressure, quite as much as it is due to the buoyancy of the heated air. From such experiments as these there has been developed the vertical suction-tube anemometer, as devised by Fletcher in 1867, re-invented by Hagmann in 1876, and introduced into England by Dines. In his Meteorological Apparatus

Marvin's Table for the Reduction of Velocities, given by the small-sized Robinson's Anemometer in gusty winds.

and Methods (Washington, 1887) Abbe gives the theory of this class of anemometers and develops the following additional forms: Two such tubes are placed one windward and the leeward, and within which are two independent barometers, give the mean of determining the barometric pressure plus the wind pressure and minus the wind pressure respectively, so that both barometric pressure, the wind and the true barometric pressure can be determined. If instead of a simple opening at the top of the tube we place there horizontally the contracted venturi's tube, we obtain a maximum wind effect, which gives an accurate measurement for the wind velocity, and is the form of venturi's tube used by Bourdon as an improvement on that of Aron. In all anemometers of this class the inertia of the moving parts is reduced to a minimum, and the measurement of rapid changes in velocity and of the maximum wind pressure becomes more accurate. Over and above these researches have shown how to expose a barometer so that it shall be free from the dynamic or wind effect even in a gale. It has only to be placed within a room or box that is connected with the outside air by a tube that ends in a pair of parallel plates. When the wind blows past the end of this tube it flows between these plates in steady linear motion, and can produce no disturbance of pressure at the mouth of the tube if the plates are at a suitable distance apart. This condition of stable flow contrasted with permanent flow, was first defined by Sir William Thomson (Lord Kelvin) (see Phil. Mag., Sept. 1887). Such a pair of small circular plates can easily be applied to a tube screwed into an air chamber, and be a barometer, and thus render it independent of the influence of the wind.

As to the exposure of the anemometer, no uniform rules have as yet been adopted. Since the wind is subject to exceedingly great disturbances, it is absolutely necessary to keep the anemometer and the rain-gauge as far as possible from the influence of large bodies. In order to estimate the force of the wind by noticing all that goes on over a large area about him has some advantage over an instrument that can only record the wind prevailing at one spot. The practice of the U.S. Weather Bureau has been to keep the anemometers free of all exposure of anemometers as high as can possibly be attained above buildings, trees and hills; but, of course, in such cases they give records for an elevated point and for the ground. These are not inapplicable to apparent conditions, but are those needed for general dynamic meteorology, and proper for comparison with the isobars and the movements of the clouds shown on the daily weather map.

Hygrometer.—Moisture floats in the atmosphere either as invisible vapour or as visible haze, mist and cloud. The presence of the latter generally assures us that the air is fully saturated. The total amount of both visible and invisible vapour contained in a unit volume of cloud or mist is directly determined by the Schwackhofer or Svenson hygrometer, or it may be ascertainment by warning a definite amount of the air and fog and measuring the tension of the vapour by Edelmann's apparatus. Both these methods, however, are in practice open to many sources of error. If only invisible aqueous vapour is present we may determine its amount by several methods: (a) the chemical method, by absorbing and weighing it; (b) the dew-point method, by cooling the air down to the temperature where condensation begins; (c) Edelmann's method, by absorbing the moisture chemically and measuring the change in vapour tension; (d) by adding vapour until the air is saturated, and measuring either the increased tension or the quantity of evaporation; (e) the psychrometric method, by determining the temperature of evaporation.

The wet-bulb thermometer, which is the essential feature of the last method, was used by Baume in 1758 and de Saussure in 1777, but merely as giving an index of the dryness of the air. The correct application of the psychrometer was first done by the inventors: Ivory, 1782; August, 1825; Apjohn, 1834; Bell, 1838; Regnault. From the last date until recent years no important progress was made in our knowledge of the subject, and it was supposed that the psychrometer was cold in the laboratory; but in its modern form it has become an instrument of much greater precision, probably quite as trustworthy as the dew-point apparatus or other method of determining atmospheric moisture. In order to determine accurately the temperature of the wet bulb, the bulb must be carefully shielded from all rising currents of hot air; and finally, both thermometers must be carefully shielded against obnoxious radiations. In order to attain these conditions European observers tend to adopt Assmann's ventilated psychrometer, but American observers adopt Arago's whirled psychrometer, set up with an ordinary thermometer shelter. By either method the dew-point should be determined with an accuracy of one-tenth degree C. or two-tenths F. As a crude approximation, we may assume that the temperature of the dew point is the same as the temperature of the wet bulb as that is below the dry bulb. A greater accuracy can be attained by the use of Ferrel's or Marvin's psychrometric tables or Grossman's formula. But the vapour tension of the dry bulb with the psychrometer was 4.75° F., which must be carefully distinguished and allowed for. The Smithsonian Meteorological Tables (ed. of 1908) and the new psychrometer tables by Bjerkland for temperatures below freezing (Christiania, 1910) are the only tables that contain the data for this subject. Glaiser deduced empirically from a large mass of observations certain factors for computing the dew-point, but these do not represent the accuracy that can be attained with the whirling apparatus. As a rule, the thermometers are used in combination with Regnault's tables and the stationary psychrometer. Especially should their use be discarded when the wet bulb is greatly depressed below the dry bulb and the atmosphere correspondingly dry. For occasional use at station and especially for use by polar explorers, nothing can exceed the convenience and accuracy of the sling psychrometer, especially if the bulbs are protected from radiation by a slight covering of non-conducting material, or even metal, as was done by Craig in 1866-1869 for the stations of the U.S. Army Surgeon-General. The hair hygrometer gives directly the relative humidity or the ratio between the moisture in the air and that which it would contain if saturated. The very delicate parts of the hygrometer are strongly recommended by Perner, and must be used in self-recording apparatus for balloons and kites; they are standardized by comparison with the ventilated psychrometer, which itself must be dependent on the standard dew-point apparatus.

Rain and Snow Gauge.—The simple instrument for catching and recording the quantity of rain, snow or hail that falls upon a definite horizontal area consists essentially of a vertical cylinder and the measuring apparatus. The receiving mouth of the cylinder is usually terminated by a cone or funnel, so that the water running down through the funnel and stored in the cylinder is protected from evaporation or other loss. The cylinder is firmly attached to the ground or building, so that the mouth is held permanently at a definite altitude.

The sources of error in its use are the scattering into it from the ground or neighbouring objects, and the loss due to the fact that when the wind blows across the side of the cylinder it produces eddies and currents that carry away droplets of rain and otherwise cause the drops that have fallen into it. As a consequence, all ordinary rain-gauges catch less than the maximum amount of rainfall. The deficit increases with the strength of the wind, is negligible for rain of ordinary size, and is increasing. The average observations with ordinary rain-gauges in western Europe, and for the averages the amount of the rain that falls in that region and the average period, of which the rain is caught by a rain-gauge whose mouth is 1 metre above the ground; and the proper amount; if its elevation is 1 ft. above ground, the deficit will be 33%. This deficit increases as the gauges are higher above the ground in proportion approximately to the square root of the altitude, it is concluded that they are fully exposed to the increase of wind that prevails at those altitudes. It is evident that even for
altitudes of 5 or 10 ft. the records become appreciably discrepant from those obtained at the surface of the ground. The following table shows in the last column the observed ratio between the catches of gauges at various altitudes and those of the respective standard stations at the level of the ground. Unfortunately, there are no records of the force of the wind to go with these measurements; but we know that in general, and on the average of many years, corresponding with those here tabulated, the velocity of the wind increases as the squares of the height above the surface of the ground. Although this deficit with increasing altitude has been fully recognized for a century, yet no effort has been made until recent years to make a proper correction or to eliminate this influence of the wind at the mouth of the gauge. Professor Joseph Henry, about 1850, recommended to the observers of the Smithsonian Institution the use of the "pit-gauge." About 1858 he recommended a so-called shielded gauge, namely—_a simple cylindrical gauge 2 in. in diameter, having a wide horizontal sheet of metal like the rim of an inverted hat_. This would undoubtedly diminish the obstructions currents of air around the mouth of the gauge, but the suggestion seems to have been overlooked by meteorologists. In 1878 Prof. F. E. Nipher of St. Louis, Missouri, constructed a much more efficient shield consisting of an umbrelliform screen of wire-cloth having about sixty-four meshes to the square inch. This shield seems to have completely annullé the splashing, and to have broken up the eddies and currents of wind. With Nipher's shielded gauges at different altitudes, or in different situations at the same altitude, the rain catch becomes very nearly uniform; but the shield is not especially good for snow, which piles up on the wire screen. Since 1888 numerous comparative observations have been made in Europe with shielded and with unshielded gauges, and with and without a shielded gauges, and with and without a shield, by Boernstein, who sought to prevent insignificant eddies about the mouth of the gauge by erecting around it a distance of 2 or 3 ft. an open board fence with its top a little higher than the mouth of the gauge. These devices taken together, but apparently afford about as good a protection as the shield of Professor Nipher, and give good results with both snow and rain.

</table>

In general it is now conceded by several high authorities that the measured rainfall must be corrected for the influence of the wind at the gauge, if the latter is not annulled by Nipher’s or Boernstein’s methods. A practicable method of measuring and allowing for the influence of the wind, without introducing any very hazardous hypothesis, was explained by Abbe in 1888 (see Symons’ Meteorological Magazine for 1888, or the U.S. Monthly Weather Review for 1889). This method consists simply in establishing near each other several similar gauges at different heights above the ground, but in otherwise similar circumstances. On the assumption that for small elevations the diminution of the wind, like that of the rainfall, is very nearly in proportion to the square root of the altitude, the difference between the records for two different altitudes may be made the basis of a correction which gives the correction to be applied to the record of the lower gauge in order to obtain the rainfall that would have been caught if there were no wind. It is only when the catch of the gauge has been properly corrected for the effect of the wind on the gauge that we obtain numbers that are proper to serve for the purpose of determining the precipitation from the rainfall, and for judging the influence of forests and the periodical changes of climate. Methods of measuring dew, frost, hail, sleet, glaties and other forms of precipitation still remain to be devised; each of these has its thermometrical value, and its importance and must eventually enter into our calculations.

It has been common to consider that the rain-gauge cannot be properly used on ships at sea, owing to the rolling and pitching of the vessel, and the interference of the rigging; but rain gauges have been mounted on the crow’s-nest of the lowest deck of the ordinary mariner’s compass, their records will be of great importance. Experimental work of this sort was done by Mohr, and afterwards in 1892 by Professor Frank Waldo; but the most extensive inquiry has been that of Mr. C. G. Black, see Journal of the Meteorological Society, 1893, vol. xiv., which satisfactorily demonstrates the practicability and importance of the marine rain-gauge.

**Evaporometer.**—The moisture in the atmosphere comes from the surface of the earth or ocean by evaporation, a process which goes on continually, replacing the moisture that is precipitated as rain, hail, snow and dew, and maintaining the total quantity of the moisture in the atmosphere at a very uniform rate. In nature, as well as in the human eye, the moisture, the dryness, and the velocity of the wind. It is not so important to meteorologists to know where the moisture comes from as to know its amount in the atmosphere, and in fact no method has yet been devised for determining how much moisture is given up by any specific portion of the earth, ocean, or forest. Our evaporometers measure the quantity of moisture given off by a specific surface of water, but it is so difficult to maintain this water under conditions the same as obtain in nature that no conclusions can be safely deduced as to the actual evaporation from natural surfaces. The proper meteorological use of these evaporometers is, as integrating hygrometers, to give the average humidity of the air, the psychrometer giving the conditions prevailing at any moment.

Among the many forms of evaporometer the most convenient is that devised by Prof. W. Boernstein and constructed as to be exceedingly accurate. The Piche evaporometer consists essentially of a glass tube, whose upper end is closed hermetically, whereas the lower end is covered by a horizontal disk of bilubulous paper, which is kept wet by absorption from the water in the tube. As the water evaporates its descent in the tube is observed, whence the volume evaporated in a unit of time becomes known. So long as the paper remains clean, and the water is pure, the records of the evaporometer are independent of the disposition of the atmosphere, the dryness of the air, and the velocity of the wind. Careful comparisons between the Piche and the various forms of absolute evaporometers were made by Professor Thomas Russell, and the results published in the U.S. Monthly Weather Review for September 1888, pp. 235-239. By placing the Piche apparatus upon a large whirling machine he was able to show the effect of the wind upon the amount of evaporation. This important datum is of course different for different parts of the apparatus established at eighteen Weather Bureau stations; based upon these results, he prepared a table of relative evaporation, formed to maintain shelters at all stations. The actual evaporation from ground and water is the sun’s contribution, and we must make allowance for the evaporation from shallow bodies of water in the sunshine, but larger for deep bodies, like the great lakes, and for running rivers. Recent studies of the evaporations from the Evaporation of the Nile, and in South Africa—but perhaps the most interesting case occurs in southern California. Here the Colorado river, having broken through its bounds, emptied itself into a great natural depression which covered the so-called "Salton Sea," about 80 m. long, 20 m. wide, and 100 ft. deep, before it could be brought under control. This sea is now isolated, and will, it is hoped, dry up in eight or ten years. Meanwhile the U.S. Weather Bureau has established a large number of evaporometers in this depression, and has begun the study not only of the relation between evaporation, wind and temperature, but of the eventual disposition of this evaporation throughout the atmosphere in the neighbourhood of the river. U.S. Monthly Weather Review, 1907-1909, also as the elaborate bibliography of evaporation in the same volumes. Although the influence of the evaporation on local climate is scarcely appreciable, yet is said to be in the development and ripening of the dates raised on the U.S. government experimental "date farm" a few miles north-east of the Salton Sea.
**APPARATUS AND METHODS**

**Meteorology**

**Nephoscope.** — The direction and apparent velocity of the motion of a cloud are best observed by means of the nephoscope, which has now become a necessary item in the outfit of any first-class meteorological station. Among the various forms of this instrument are the nephoscopes of Fornioni, the marine nephoscope of Fineman, the simple mirror with attachments used by Clayton, the cloud camera of Vettin, and the altazimuths of Mohn and Lettry. The most perfect form for use on land is that devised by Professor Marvin in 1896 for the U.S. Weather Bureau stations (see fig. 2); while the most convenient for use at sea is that devised and used in 1899 by Professor Abbe on the cruise of the U.S. ship "Pensacola" to the west coast of Africa, but first described in the report of the International Meteorological Congress held at Chicago in August 1893.

The construction of this instrument is shown in figs. 3, 4, 5. In using it the observer looks down upon a horizontal mirror and observes the reflection of the cloud. By moving his eye he brings any cloud point into coincidence with the reflection of a small fixed spherical knob K above the mirror, and keeps the images of the knob and the cloud coincident as they pass from the center of the mirror. This line of motion shows the azimuth of the horizontal component of the cloud's motion. The course of the vessel is shown by the compass card and linear line AF seen below the mirror. The apparent angular velocity of the cloud, as it would be the cloud, is limited from the zenith, is obtained by counting the seconds that elapse between its passage from the center to the edge, or to a small circle inscribed within the edge. With Marvin's nephoscope two observers a short distance apart may easily determine the apparent altitude and azimuth, and motion of any of the clouds. If the vessel is under his control, so that he may change its velocity or direction at will, he easily determines the resultant for two different courses, and obtains data by which he is enabled to calculate the real altitude and velocity of the cloud in terms of his own motion. As the marine nephoscope is used on a wagon moving rapidly over a smooth road, or in a small boat on a smooth pond, almost as well as on a larger sea-going vessel, it becomes an instrument of universal application for cloud study. It is also equally convenient for observing the position of auroras, haloes, and other special phenomena. For the international work undertaken during the year 1898 the photograph camera established upon an alt-azimuth mounting, or the so-called photo-gram-meter, was especially developed. In this apparatus photographs of the clouds are taken simultaneously at two or more stations, and in each case the centre of the photograph plate has its altitude and azimuth determined. From this centre one can measure on the plate the additional angles required in order to fix the altitude and azimuth of any point that is photographed, and thus the dimensions of the whole visible cloud and its internal or differential motions can be determined, as well as its general motion.

During the years 1860-1869 about twenty stations were occupied throughout the world for the purpose of determining accurately the altitudes and motions of every layer of cloud.

**Sunshine Recorder.** — The ordinary meteorological record specifies the proportion of sky that appears to be covered with cloud, or the so-called cloudiness, usually expressed in tenths. The observer generally confines his attention to that portion of the sky within sixty degrees of the zenith, and ignores the lower zone, since the clouds that are found therein are often at so great a distance from him that their record is not supposed to belong to his locality. As the cloudiness—or its reciprocal, the sunshine—is supposed to be the most important item in agricultural climatology, and is certainly very important for dynamic meteorology, it is usually considered desirable to obtain more complete records than are given by only one or two specified hours of observation. To this end apparatus for recording sunshine, or, rather, the effect of cloudiness, is widely adopted. At least three forms are worth describing as being extensively used.

The Jordan photographic sunshine recorder consists of a cylinder enclosing a sheet of sensitive paper; the sun's rays penetrate through a small aperture and are reflected from a prism to a spot which appears on this sheet after it has been properly washed with the fixing solution. Any interruption in this path, due to cloudiness or haze, is of course clearly shown, and gives at once the means of estimating the periods during which the sun was clear or cloudy.

The modified form of the instrument devised by Professor Marvin has been used for many years at about forty Weather Bureau stations, but the original construction is still employed by other observers throughout the world. The "Stokes-Campbell Recorder" consists of a globe of glass acting as a burning-glass. A sheet of pasteboard or a block of wood at the rear receives the record, and the extent of the charring gives a crude measure of the percentage of full or strong sunshine. Observations of the differential effect are then obtained in the same way.

The "Lambert-Thompson Recorder" consists of a thermistor tube, having a black bulb at the lower end and a bright bulb at the other. The excess of temperature of the dark bulb above that of the bright bulb is thus a measure of the relative or differential cloudiness, and for a certain standard difference of temperature of about 5° F., such as would be produced by the sun shining through a very thin cloud or haze, a record is made by an electric current on a revolving drum, and shows how the intensity of the sunshine varies from one moment to another. The intensity of the sunshine may be obtained from a comparison with the intensity of any standard source, such as a blackened and polished copper bulb, or a yellow and black stoplight bulb, and the readings of the two bulbs are then recorded on a continuous strip of paper. The "Arago-Davy Actinometer" consists of a bright bulb and a black bulb, and a photographic plate is exposed in the two bulbs alternately, the total number of exposures being divided by two in order to get the average for two bulbs. The "Davies Actinometer" has a blackened bulb in a small tube, and a photographic plate is exposed for one second with the black bulb and for another second with the white bulb, and the plate is developed and exposed to light in a dark room.
METEOROLOGY

APPARATUS AND METHODS

on the intensity of the solar radiation at two points, respectively, 360 and 3352 metres above sea-level, and determined the amount of heat absorbed by the intermediate atmosphere. An accuracy of 1-1000 appears to be attainable, and this apparatus is now being widely used. The records of 1901-1905 have already given rise to the belief that there is a variation in our insolation that may eventually be traced back to the sun's atmosphere.

**Meteorograph.**—The numerous forms of apparatus designed to keep frequent or continuous register of the prevailing pressure, temperature, moisture, wind, rainfall, sunshine, evaporation, and other phenomena are instruments that belong peculiarly to meteorology as distinguished from laboratory physics. Such apparatus may be broadly divided into several classes according as the records are obtained by the help of photography, or electricity, or by direct mechanical action. The prevailing tendency at present is in favour of apparatus in which the work of the recording pen is done by a falling weight, whose action is timed and limited by the making and breaking of electric currents by the meteorological apparatus proper. The most serious defect in such instruments, even when kept in good working order, is a want of sensitiveness commensurate with the desired openness of scale. It is very important that a fraction of a minute of time should be as recognizable as one-tenth of a degree of temperature; one thousandth of an inch of barometric pressure, and velocities of one hundred miles per hour, as well as rapid changes in all these elements, must be measurable. But instruments whose scales are large enough to record all these quantities are usually so sluggish as regards time that the comparison of the records is very unsatisfactory. In order to study the relationships between temporary and fleeting phenomena, it is necessary that all instruments should record upon the same sheet of paper, so that the same time-scale will answer for all.

The instruments that respond most nearly to the general needs of meteorology are the various forms of meteorographs devised by Wild for use at St Petersburg, by Sprung and Fuess for use at Hamburg and Berlin, and by Marvin for Washington. The photographic systems for pressure and temperature introduced many years ago in the districts in Great Britain and the British colonies are not quite adequate to present needs. The portable apparatus manufactured by Richard Frères at Paris is in use at a very large number of land stations and on the ocean, and by giving special care to regular control-observations of time, pressure and temperature, important results may be obtained; but in general the timescales are too small, and the unknown sources of error too uncertain, to warrant implicit reliance upon the records.

**Polarimeter.**—The brightness and blueness of the sky light, and especially its polarization, have been observed with increasing interest, as it seems possible from these elements to ascertain something with regard to the condition and amount of the moisture of the air. With a simple Nicol’s prism held in the hand and turned slowly about the axis of vision one can quickly recognize the fact that the sky light is polarized, and that the polarization is largely due to the air or dust lying between us and the clouds in the distant horizon. Arago, with a more delicate apparatus, determined the existence of a so-called neutral region near the sun. Babinet located a neutral point or zone as far from the anti-sun as was Arago’s from the sun itself. Brewster discovered a neutral point near the sun and horizon, disappearing when the sun is more than 15° above the horizon. Finally, Brewster explored the sky sufficiently to draw lines of equal polarization, which he published in Johnston’s Physical Atlas, and which were confirmed by Zantedeschi in 1849. Since those days far more delicate work has been done—first by Bosanquet of Oxford, afterwards by Prof. E. C. Pickering of Harvard University and Prof. A. W. Wright of Yale University. A later contribution to the subject is by Jensen (see Met. Zeit. for Oct.-Dec. 1890), who has observed the brightness as well as the polarization, and thus completed the data necessary for testing the various physical theories that have been proposed for the explanation of this phenomenon. We owe to Tyndall the discovery that when a beam of white light penetrates a mass of fine aqueous mist the latter sends off at right angles a delicate blue light, which is almost wholly polarized in a plane at right angles to the plane
of reflection. As the particles of mist grow larger, the blue light becomes whiter and the polarization disappears. The original vapour particles are undoubtedly so small as to be comparable in size with a fraction of the wavelength of ordinary light, and Rayleigh was able to show that molecular as well as minute particles must have a power of selection, and that the diffused sky light comes to us by selective reflection. On this basis we should expect that in the driest air at great heights, where the temperature is low and condensation has but just begun, and the dust particles are rare, there would occur the smallest aqueous particles reflecting light of the feeblest intensity but the largest percentage of polarization. Rayleigh has shown that it is quite possible that the molecules of oxygen and nitrogen constituting the atmosphere may also exercise a diffuse selective reflection, and contribute to the brightness and polarization that are mainly due to aqueous vapours. (See Sky.)

We shall see the theoretical importance of adding photometry and polarimetry to the work of a meteorological observatory. The apparatus to be used in this connexion will vary somewhat with the exact character of the observations to be made. Those extensive investigations that have yet been carried out on this line with a mirror galvanometer in London are those of Cornu, Pickering, Kimball, Nichols, and especially Rubenon, who in fact recommended that polarimetry and photometry should go hand in hand. In order to measure the position of the plane of polarization of the light reflected by a photographic plate, we may use a galvanometer to measure the percentage of polarized light, Mascart's modification of the Savart is better. In order to measure the general brightness of a spot in the sky, Jensen has used a slight modification of the Weertman galvanometer, and in fact, the instrument has already been used in the measurement of the daylight. The complete work of Jensen was published in the "Schriften" of the Scientific Association of Schleswig-Holstein in 1899, and, like the memoir published by Rubenon in 1893, it gives the meteorological conditions in full as a basis for the investigation of the connection between sky light and the moisture in the atmosphere. In his work during 1899-1900, Angström's pyrheliometer Mr. A. H. Kimball of Washington has advantageously used the Pickering polarimeter, and has shown that the transparency of the air and the polarization of light go hand in hand.

Cyanometer.—The cyanometer devised by Arago to measure the blueness of the sky consisted of an arbitrary scale of blues on a strip of porcelain, with which one could compare the blue of the sky. This comparison, however, is open to many subjective errors. A more satisfactory apparatus is Zollner's photometer, or some equivalent, in which a patch of white surface is illuminated by any particular tint or combination that may be desired. In fact, Maxwell's colour-blind admits of a modification to the analysis of sky light, and reveals, at once, the proportions of red, yellow, and blue that may be contained therein.

Dust-counter.—The importance of observing the dustiness of the atmosphere has been especially realized since the invention and use of various forms of apparatus for counting the number of particles of dust in a small volume of air. These inventions are due to Mr John Aitken, of Edinburgh.

The latest form of his apparatus is the very convenient "pocket dust-counter." In this the air contained in a small receiver is rendered dustless by repelling the dust in the cooling of the air; it then forces the vapour to condense upon the dust, which, becoming heavy, falls to the bottom, so that in a short time all is removed. A small stop-cock is now turned, so as to allow a definite amount of air to enter and mix with the dustless air in the receiving vessel. This dustless air is now thoroughly mixed, and again the whole quantity within the receiver is expanded, and the dust nuclei fall down by the condensation of vapour upon them. Assuming that every particle of dust is represented by a minute droplet of water, we have to count the latter; this is easily done by causing all the drops to fall upon a polished plate of black glass which is divided into small squares by fine lines ruled with a diamond point. Usually each of these squares represents a small fraction of a cubic centimetre of air; thus, in one case the number of four particles averaged 2.6 per square millimetre of the glass plate, and, as the multiplying factor was 100, this corresponded to 260 particles of dust in a cubic centimetre of air. The cleanest air has been found in the mountain air of the Weimer. The Highlands of Scotland, where 16 particles per cubic centimetre was once recorded as the minimum, while 7600 was the maximum. On the Rigi Kulm, in Switzerland, the cleanest air gave 210, and the dustiest 16,500. On comparing the records of the dust-counter with the record of the apparent state of the air, Mr. Aitken found that 500 particles per cubic centimetre corresponded to clear air, and 1900 to a thick haze in which distant mountain tops were hidden. In the cities the particles of soot and effluvia of all kinds act as dust, and both in London and Paris the numbers ran as high as 80, 116, 1200 and 5000.

Electrical Apparatus.—The electrical phenomena of the atmosphere undoubtedly belong to meteorology, and yet the methods of observation have been so unsatisfactory and the difficulty of interpreting the results has been so baffling that regular observations in electricity are only carried out at a very few meteorological institutions. A general summary of our knowledge of the subject was prepared by J. Elster and H. Geitel for the International Congress held at Chicago in 1893, but since that date the methods and apparatus of observation have received important modifications.

In general the water-dropping collector of Lord Kelvin, arranged for continuous record by Mascart, continues to be the best apparatus for continuous observation at any locality, and a portable form of this same apparatus is used by explorers and in special series of local observations. In order to explore the upper air the kite continues to be used, as was done by A. J. McAdie for the Weather Bureau in 1885 and by Weber at Kiel in 1889. The difference of potential between the upper and lower end of a long vertical wire hanging from a balloon has been measured up to considerable altitudes by Elster and Tuma. In general it is known that negative electricity must be present in the upper strata just as it is in the earth, while the intervening layer of air is positively electrified. The explanation of the origin of this condition of affairs is given in the recent researches of Sir J. J. Thomson (Phil. Mag., Dec. 1899), and his interpretation

![Fig. 6.—Marvin-Hargrave Kite, with Meteorograph in position.](image-url)
studying the depth of the ocean breeze on the coast of New Jersey, but the later revival of interest in the subject dates from the work done in England in 1882 by E. D. Archibald, who used the kite to carry up anemometers to very considerable heights, and thereby determined the relative movement of the air in the free atmosphere. In 1883 Alexander McAdie used the kite in his studies of atmospheric electricity, Professor Cleveland Abbe proposed to use it for a complete exploration as to temperature, moisture and wind, but W. A. Eddy of New York first forced its varied capabilities upon public attention, and accepted the suggestion of Professor Cleveland Abbe to employ it for meteorological work. Having flown his kites at the Blue Hill Observatory, and having carried up with them the self-registering apparatus devised by Mr. Ferguson, Eddy left the further prosecution of this work to Mr. Rotch, who has made this a prominent feature of the work at his observatory, having carried up meteorographs to the height of 15,000 feet by means of a series of kites flying in tandem. The officials of the U.S. Weather Bureau have developed the admirable cellular kite, invented by Hargrave of Australia, and Professor Marvin's works on the theory and construction of this form are well known.

The general appearance of the Marvin or Weather Bureau kite, his reel and other apparatus that go with it, and his meteorograph, are shown in Figs. 6, 7, 8. The size ordinarily used carries about 68 sq. ft. of supporting surface of muslin tightly stretched on a light wooden frame. The line, made of the best steel piano-wire, is wound and unwound from a reel which keeps an automatic record of the intensity and direction of the pull. The reeling in and out may be done by hand, but ordinarily demands a small gas-engine. The observer at the reel makes frequent records of the temperature, pressure and wind, the apparent angular elevation of the kite, and the length of wire that is played out. At the kite itself the Marvin meteorograph keeps a continuous record of the pressure, tempera-

ture, humidity and velocity of the wind. The meteorograph, with its aluminum case, weighs about two pounds, and is so securely lashed behind the front cell of the kite that no accident has ever happened to one, although the kites sometimes break loose and settle to the ground in a broken country many miles away from the reel. On four occasions the line has been completely destroyed by slight discharges of lightning; but in no case has the kite, the observer, or the reel been injured thereby. Of course, such lightning is preceded by numerous rapidly increasing sparks of electricity from the lower end of the wire, which warn the observer of danger. During the six months from May to October 1898, seventeen kite stations were maintained by the U.S. Weather Bureau in the region of the lakes, the Upper Mississippi and the Lower Missouri valleys, in order to obtain data for the more thorough study of atmospheric conditions over this particular part of the country. During these months 127 ascents were made, and as no great height was attempted they were mostly under 7000 or 8000 feet. There was thus obtained a large amount of information relating to the air within a mile of the earth's surface. The general gradients of temperature, which were promptly deduced and published by H. C. Frankenfield in 1899 in a bulletin of the Weather Bureau, gave for the first time in the history of meteorology trustworthy observations of air temperatures in the free atmosphere in numbers sufficient to indicate the normal condition of the air.

The kite and meteorograph have now been adopted for use by all meteorologists. The highest flight seems to be that of the 3rd of October 1907, at Mt. Weather in Virginia, when 23,110 ft. above sea-level or 21,385 ft. above the reel was attained by the use of 37,300 ft. of wire and 8 kites tandem.

The balloon was used for the scientific exploration of the atmosphere quite freely during the 19th century. The first important voyages were those of Gay-Lussac and Biot at Paris in August and September of 1804. The next important ascent was that of Bixio and Barral in 1850 at Paris. The most remarkable high ascents have been those of James Glaishe, 2nd of September 1862, and Benson at Berlin in 1880; on both of these occasions the aeronauts attained altitudes of from 30,000 to 35,000 feet. Systematic ascents at many points in Europe simultaneously on pre-arranged dates were made during the years 1895-1899, and led to the development of a general international system of ascension on pre-arranged days of the year that is now a very important feature in the study of the atmosphere.

![Fig. 7.—Marvin Kite Reel for hand power.](image1)

![Fig. 8.—Marvin Kite Meteorograph.](image2)

![Fig. 9.——Chart of Isotherms in Free Air above Trappes.](image3)
Such balloon soundings have been made not only individually, but, by pre-arranged system, simultaneously in combination with the ascent of free-manned balloons above referred to; and at some places kites have been simultaneously used in order to obtain records for the lower layer. The first kites were made in 1896 and 1897, when ascents were made at eight or more points in France, Germany and Russia. These experiments and the discussions to which they gave rise have emphasized the importance of the accurate determination of the atmospheric temperature, and as far as practicable the rapidity of the ventilation of the thermometers, and of providing more perfect protection against radiation from the sun or to the sky. It is believed that accurate temperature records have now been made, at least so far as yet only 26,000 has been attained, and the records brought back are still under considerable criticism on account of instrumental defects. In general the wind that supports a kite also furnishes sufficient lift to carry the kite to the required altitude. As to the sounding balloon, which as soon as its rapid rate of ascent diminishes floats along horizontally in the full sunshine, a strong artificial ventilation must be provided. Moreover, the sluggishness of the best in instruments was such that, as long as the records of temperature that are being made at any moment really belong to some altitude considerably below the balloon, and a most critical interpretation of the records is required. Notwithstanding all these criticisms, however, the balloon work in all localities agrees in showing the existence of a region above the 10,000-metre level, where temperatures cease to diminish rapidly, and may even become stationary.

III.—PHYSICAL AND THEORETICAL METEOROLOGY

The ultimate aim of those who are devoted to any branch of science is to penetrate beyond the phenomena observed on the surface to their ultimate causes, and to reduce the whole complex of observations and empirical rules based upon limited experiences to a simple deductive system of mechanisms in which the phenomena observed shall be shown to flow naturally from the few simple laws that underlie the structure of the universe. A correct theory or physical and logical argument deduced from them is the highest form of scientific knowledge, and one of the noblest achievements of man in science. It is by such works that Newton and Laplace distinguished themselves in astronomy. The development of the true physical and mechanical theories of atmospheric phenomena has made great progress, but is still inferior in completeness to astronomical work, owing to the great complexity of the meteorological problems. The optical and thermal phenomena have been very satisfactorily elucidated, the electrical phenomena promise to become clear, but the phenomena of motion or aerodynamics have only been elucidated to a limited extent. We must, however, introduce the reader to some of the works that have been published on the subject, in the hope that thereby he will himself be persuaded to further study and stimulated to contribute to our knowledge.

Between the years 1853 and 1861 Professor William Ferrel published several papers in the ‘Candian Journal of Science’ and the ‘American Journal of Science’ on the motions of solids and fluids relative to the earth’s surface. His work resulted in the elucidation of the problems of the atmosphere, and the development of the fundamental formulae of mechanics. A beautiful memoir on the steady motions of the atmosphere was published in 1868 in the ‘Astronomische Nachrichten’ by Professor Adolph Ermann, and is now reprinted in vol. ii. of Airé’s ‘Mechanics of the Earth’s Atmosphere.’ Esps’s, Coffin’s, Henry’s and Ferrel’s ideas were the basis of the system of daily weather predictions published by the first writer in 1896 in the ‘Daily Weather Bulletin’ of the Cincinnati Observatory. These ideas were expanded and greatly enlarged during 1871–1872 by the chief signal officers of the army, and after 1871 by the chiefs of the U.S. Weather Bureau. Ferrel’s writings first attracted the attention of European meteorologists in 1873, when they were published by Hermann von Helmholtz in the ‘Zeitschrift’ of the Austrian Meteorological Society in January 1875, but especially after they had been reprinted in a convenient form by Angstrom. The whole system of Ferrel, after finishing his works on the tides for the U.S. Coast and Geodetic Survey, began a new and extensive series of meteorological contributions, three of which were published by the U.S. Coast Survey and the rest by the Signal Office. Stimulated by the urgent needs of the modern weather bureaus throughout the world, and by the beauty of the mathematical problems presented, numerous mathematicians have lately taken up the study of the earth’s atmosphere, so that the literature of the subject is now far more extensive than that of any other branch of meteorology. Memoirs have been published by Dr. Langley, Hutchins, Angstrom, Paschen, Vielle, Maurer, Crova, Chwolson, Very, Homin, Tamura, Trabert and Coblenz. The thermodynamic problems have been especially treated by Helmholtz, Hertz, Kelvin, Brillouin, Neugebauer, Bigelow and Margules. The physical problems involved in the formation of rain-drops have been studied by an optical method by Carl Barus, and with brilliant success, from an electrical point of view by Sir J. J. Thomson at the Cavendish Laboratory, Cambridge, England.

In a complete study of the mechanics of the earth’s atmosphere we naturally begin by expressing in simple analytic formulae all the various conditions and laws according to which every particle of the air must move. Some of these conditions are local, depending upon the resistances at various points of the earth’s surface; others are of the nature of discontinuous functions, as, for instance, when the ascent of moist air above a certain level suddenly gives rise to condensation and clouds, to the evolution of latent heat, to the precipitation of rain, to the shading of the air and the ground below the clouds, and to the sudden interception of all the solar heat at the top of the cloud. It is necessary to consider that the problems of the atmosphere can ever be resolved by purely analytical methods; there must be devised combinations of numerical and graphical, and possibly even mechanical methods to reproduce the phenomena and give the solutions in all the particular cases. But even these special methods can only be perfected in proportion as we attain approximate solutions of the simpler problems, and it is in this preliminary work that a good beginning has already been made.

The present state of theoretical physical and mechanical meteorology cannot be fully presented in non-technical English text. It is necessary to employ algebraic formulae, or numerical tables, or graphic diagrams, the former being certainly the least cumbersome and the most generally available. The uniform system of notation devised by Professor F. H. Bigelow, and a very complete summary of the formulae of physical meteorology expressing the results of many recent students will be found in chapters x. and xi. of his Report on the International Cloud Observations, published as vol. ii. of the annual report of the chief of the U.S. Weather Bureau for 1898–1899.

The fundamental laws to which the atmosphere is subject are as follows:

A. The Equation of Elastic Pressure.—The pressure shown on meteorological barometers is an elastic pressure, which is equal in all directions at the point where it is measured. By virtue of this elastic pressure a unit volume of air will expand in all directions if not rigidly enclosed, but will cool in so doing. On the other hand, an atmosphere in compression will become warmer. For a given temperature and pressure a unit volume of air of a prescribed chemical constitution will have a prescribed definite weight. The general relations between absolute temperature, pressure and volume are expressed by the formula

$$pV = RT$$

where $T$ expresses the absolute temperature, $p$ the elastic pressure, $V$ the volume, and $R$ is a constant which differs for each gas, being 29.2713 for ordinary pure dry air and 47.060 for pure aqueous vapour, if we use as fundamental units the kilogram, metre and second. This relation is usually known as Gay-Lussac’s law of volume and pressure. It is sometimes called the Boyle and Charles, or of Gay-Lussac and Mariotte, and it is also known as the equation of condition for true gases, meaning thereby that it expresses the fact that the ideal gas would change its volume directly in proportion to its absolute temperature and inversely in proportion to its elastic pressure. All gases depart from this law in proportion as they approach the vapid condition on the one hand, which is brought about by great pressure and low temperature, and the absolute condition on the other hand, which obtains under high temperatures and low pressures. The more accurate law of Van der Waals would complicate our problems too much. In place of the absolute temperature $T$, let the expression

$$T = T^* (1 - b a / V^2)$$

be used, where $T^*$ is the absolute temperature, $V$ is the volume, $b$ and $a$ are constants, and $V^*$ is an arbitrary volume, which, when the gas is compressed, will be in the same proportion as the original gas. The equation of condition for an ideal gas is:

$$pV = RT$$

where $T$ is the temperature expressed on the centigrade scale.

B. Hypsometric Conditions.—An atmosphere at any place depends primarily on the weight of the superincumbent mass of air, and therefore diminishes as we ascend to greater heights. If the air is in motion, that and other considerations come in to affect the pressure; but if the air is quiet relative to the earth’s
surface, then the pressure at any altitude is expressed by the so-called barometric or hypsometric formula

\[ p = \int_{0}^{s} -\sigma dh \]  

(2)

where \( \sigma \) is the density and \( h \) the apparent gravity for each layer of air where vertical thickness is \( dh \). The integral of this formula depends upon the vertical distribution of temperature, moisture and motion, and is valid only for the assumption that these vertical gradients, the following formula was deduced by Laplace and is generally known as his hypsometric formula:

\[ \begin{aligned}
&k - h = 18400(1 - 0.000367)(1 + 0.0375 p)(1 - 0.00026 \cos 2\theta) \\
&\frac{(k - h)}{h} = (1 + 0.00157) \log p
\end{aligned} \]  

(2a)

In this formula \( k \) is the average temperature, \( e \) the average vapour tension of the layer of air, \( p \) the barometric pressure at the top of the layer, \( \rho \) the pressure at the bottom, \( \phi \) the latitude of the station, \( h \) the elevation above sea-level of the lower limit of the stratum, and \( k \) and \( h \) the heights of corresponding temperature, and the two quantities which this formula needs in order to adapt it to other hypotheses representing more nearly the actual distribution of temperature, moisture and gravity, have been elaborately investigated by Angot in a memoir published in 1899 in Part I. of the Memoirs of the Central Meteorological Bureau of France for the year 1896. Angot, Hergesell and Rykat-kehr have also shown that for hypsometric work of any pretensions to accuracy it is simplest and best to use Laplace’s formula for successive thin strata of air, and add together the individual results, rather than attempt a more complex single formula for the whole stratum; yet the latter seems to be essential for work in aerodynamics.

C. Thermodynamic Relations.—The temperature of the air is due to the quantity of molecular energy that is present in the form of heat, but usually there is also present a quantity of molecular energy that is spoken of as latent heat. This latent heat is said to do internal work, such as melting ice or boiling water, while the sensible heat does external work, such as expanding and pushing in all directions. These molecular energies can be transformed into each other over and over again without appreciable loss, and this power of transformation is expressed by the various equations of thermodynamics, of which the fundamental one for our purpose is

\[ \text{d}Q = C_d \text{d}t + A \text{d}p = C_d \text{d}t + \text{ART} \text{d}t. \]  

(3)

This equation expresses the fact that when a quantity of heat measured in calories, \( \text{d}Q \), is added to or taken from a mass of dry air, there may result both a change of temperature, \( \text{d}t \), corresponding to one portion of the heat, \( C_d \text{d}t \), and a quantity of external work, \( A \text{d}p \), corresponding to the other portion. In the present condition of the heat portion it usually happens that the quantity of heat in a given mass of air does not remain the same for any length of time; it is diminished by radiation or is increased by absorption, and a certain quantity is lost when rain or other hygroscopic moisture condenses a drop of water. Each of these changes is represented by a term in the above equation, and is implied in the process of integration, and in the equation of continuity

\[ \begin{aligned}
&\frac{\partial p}{\partial t} + \frac{\partial (p v)}{\partial x} + \frac{\partial (p w)}{\partial y} + \frac{\partial (p w)}{\partial z} = 0 \\
&\text{where } p \text{ is the density, } t \text{ the time and } \partial \text{ the ordinary symbol for partial differentiation. But the fact is that meteorologists have to do with quantities having certain processes that occur at sunset and renewed daily; radiations of heat changing abruptly with land and ocean and cloudiness and snow covering; discontinuous boundary conditions and resistances at the earth’s surface, in addition to the hypsometric formula, it is as ceasing at sunset and renewed daily; radiations of heat changing abruptly with land and ocean and cloudiness and snow covering; discontinuous boundary conditions and resistances at the earth’s surface.} 
\end{aligned} \]  

(4)

or extent of area are the rotation of the earth and the principle of gravitation. In the presence of such difficulties as these we must at present confine ourselves to the solution of special local definite problems or to the general statistical problems of our atmosphere.

E. Conditions as to Energy and Motion.—When the total quantity of heat, both latent and sensible, remains constant or changes in a continuous manner, and when the motions are continuous, the mechanical and thermal processes may be derived from the partial differential equations and integrals. Motions of fluids involve both energy and inertia, and are subject to conditions expressed by the following equations of hydrodynamics:

\[ \begin{aligned}
&\frac{\partial (T + V^2 + W^2)}{\partial t} = \int (\text{i} \text{u} + \text{m} \text{v} + \text{n} \text{w}) \text{dS}. \\
&\text{Equations of acceleration and inertia. Let } P \text{ be the potential of the external forces acting on a unit mass of the atmosphere; } \mu \text{ be the coefficient of viscosity or internal friction. Then will} \\
&\frac{\partial P}{\partial x} - \frac{\partial (P \text{u})}{\partial x} = -\sigma \text{u} + \sigma \text{v} + \sigma \text{w} + \frac{\partial (\mu \text{u})}{\partial x} + \frac{\partial (\mu \text{u})}{\partial y} + \frac{\partial (\mu \text{u})}{\partial z} \\
&\frac{\partial P}{\partial y} - \frac{\partial (P \text{v})}{\partial y} = -\sigma \text{v} + \sigma \text{u} + \sigma \text{w} + \frac{\partial (\mu \text{v})}{\partial x} + \frac{\partial (\mu \text{v})}{\partial y} + \frac{\partial (\mu \text{v})}{\partial z} \\
&\frac{\partial P}{\partial z} - \frac{\partial (P \text{w})}{\partial z} = -\sigma \text{w} + \sigma \text{u} + \sigma \text{v} + \frac{\partial (\mu \text{w})}{\partial x} + \frac{\partial (\mu \text{w})}{\partial y} + \frac{\partial (\mu \text{w})}{\partial z} \\
&\text{Approximate Assumptions and Solutions.—After introducing into the preceding system of fundamental equations (1–6) the actual conditions as accurately as they are known relative to gravity, solar radiation, the rotation of the earth, the viscosity of the atmosphere, it is necessary to decrease the temperature, and its boundary conditions as between the rough earth surface on its lower side and the unknown outward surface of the atmosphere.}} 
\end{aligned} \]  

(5)

The treatment of atmospheric problems by Ferrel was followed by an extensive and successful treatment by Liouville, Guteberg and Mohn, of Christiana, in two papers published by them in 1876 and 1880 respectively. These authors, like Ferrel, treat isolated portions of the atmosphere and obtain special solutions, which, however, have not the generality that the method of integro-differential equations and the discontinuous of the atmosphere requires. Elegant mathematical solutions of our problems were first given in 1882 by Oberbeck, of the university of Halle, in the Ann. Phys. xvii. 128. But even Oberbeck’s solutions are obtained under various simplifications that have been satisfactorily applied, for example, the daily weather conditions. Oberbeck’s first memoir treats of the mechanics of stationary cyclical movements. Assuming that the isobars are concentric circles, and that in the inner portion of the atmosphere in the inner region of the centre outwards to the limit of the inner region, where it diminishes in the outer region and at a great distance becomes inappreciable. In both regions the paths of the wind are curved lines, logarithmic spirals, which cut the isobars or the radial gradient everywhere at the same angle; therefore the movement of the air can be considered as a spiral inflow from all sides towards the centre. But the angle between the wind and the gradient follows different laws in the outer and inner regions, depending on the former the rotation of the
earth and the friction, but in the latter also on the intensity of the ascending current of air. In passing from the outer to the inner surface the wind experiences a sudden change of angle, so that the directions of the winds are not continuous, although the movement and velocity of them are. It appears as if the changes of the air could be divided into two major categories. In the former, the winds at the surface, which may be considered as a plane having a uniform diurnal rotation and a uniform coefficient of friction. Moreover, the movements in the cyclones and anti-cyclones are assumed to be steady and unaffected by the complex meteorological processes involved therein. Of course these conditions are not exactly fulfilled, but in general Pockels shows that his theoretical results agree fairly well with the observed conditions as to wind and pressure. He computes the actual distribution of pressure in a cyclonic atmosphere under the assumption that the anti-cyclone is at latitude 55-5, and that the coefficient of friction is 0-0008, whereas viscosity proper would require only 0-0002. An elegant mathematical presentation of these studies in cyclonic motion is given by W. Wien, Lehrbuch der Wetterkunde (Leipzig, 1900).

Notwithstanding the fact that these difficult mathematical investigations still lead us to unsatisfactory results, they are yet eminently instructive as showing the methods of interaction of the various influences. It is clear that, in the cyclonic atmosphere, there must therefore mention the interesting attack made by Oberbeck upon the problem of the general circulation of the atmosphere. His memoir on this subject was published in the Sitzungsberichte of the German Scientific Society in 1859. The general assumption in this memoir implies that there is a general and simple system of circulation between the equatorial and the polar regions, but the eventual solution of the problem leads Oberbeck to two independent theories. The first, and the better known of these for its simplicity, is that the distribution of temperature throughout the atmosphere in both the upper and lower strata can be represented by the equation $T = A + B (1 - 3 \cos^2 \theta)$. Undoubtedly this equation represents observations in the lower strata near the surface of the earth, but the constants that enter into it, if not the form itself, must be changed for the upper strata. The solution arrived at by Oberbeck gives the following equations representing the components of movement: $V = C (1 - 3 \cos^2 \theta)$, $\theta = 0$, $\phi = 0$, $\psi = 0$. In accordance with these equations he deduces the general circulation of the atmosphere as follows: In the lower current the air flows from the polar regions earthward until it reaches the parallel of 30°, and thence cyclonically toward the equator. It then ascends equatorward until, at the equator it becomes a strong east wind (or a so-called west current). In the upper layer the movement begins as an east wind, turns rapidly to the north at latitude 20°, descends towards the equator in the northern hemisphere, but a north-west wind (or north-east current) in the southern hemisphere. Of course the higher strata of the atmosphere must diminish in strength. In a second paper, Oberbeck published in 1869 a more complete theory of the general circulation of the atmosphere. He is of the opinion that a knowledge of the pressure on the earth's surface is as far as it is consistent with his system of temperatures and winds. His general equation shows that as we depart from the equator the pressure must depend upon the sine of the latitude, the cosine of the longitude relative to the earth, i.e., $0-0292 (\sin \phi - 0-0836)$, which is quite small and is a maximum (4-6 metres per second) at latitude $S$, $60^\circ 27'$. H. Hildebrandsson (1906) showed that observations do reveal an east wind prevailing along the equatorial belt of the world. No other attempts to present, as those by Professor Duro Kitao, of the university of Tokyo, who, as a student of mathematics in Germany, had become an expert in the modern treatment of hydrodynamic problems. In three memoirs published by the Agricultural College of the university of Tokyo in the German language in the years 1887, 1889 and 1895, he develops with great patience many of the minuta of the movement of the earth's atmosphere and cycnonic storms. The assumptions under which he conducts his investigations do not depart from nature quite so far as those adopted by other mathematicians. Like Ferrel, he adheres as closely as possible to the results of physical and meteorological observations; and although, like all pure mathematicians, he is content to introduce new methods, he is found to be the most solidly based mathematician. He also unites with them in acknowledging that the results attained by Ferrel harmonize with the meteorology of the earth.

The general circulation is the solution of the hydrodynamic equations is not unique, but multiple. Every system of initial and boundary conditions must give a solution appropriate and peculiar to itself. The actual atmosphere presents us with the solution or solutions that profoundly differ from each other, and is furthermore dependent on the different conditions that prevail far the earth. It is possible by mathematical methods, yet he even unites with them in acknowledging that the results attained by Ferrel harmonize with the meteorology of the earth.

of upper winds shown by the higher clouds, namely, south-westerly in the northern hemisphere and north-westerly in the southern.

Halley in 1680, and Hadley in 1735, gave erroneous or imperfect explanations of the mechanical principles that bring about these winds; and in regard to the whole subject, it is necessary to say that it is erroneous to teach that atmospheric air weighs less on being heated, or by reason of the infusion of more moisture, and that therefore the barometer falls. The addition of moisture increases its weight, as a whole atmosphere must always be deflected counter-clockwise around the earth’s axis, while at the same time it may be circulating about a storm centre. Inappreciable differences of pressure start the winds in motion, and the air moves towards the region of lower pressure. As these differences increase, the winds move towards the low pressure carries the packages along. But in the free air, where there are less important resistances to be overcome, the freedom of motion is greater than in these pneumatic tubes. The same is true of the air moving upwards from the earth’s surface. In the case of the increase in pressure, the wind warm the low to the earth's surface. This is the basic reason why the wind is deflected to the right by the Coriolis force.

The Coriolis force is a consequence of the rotation of the earth. It is the horizontal force that acts on a moving object in the Northern Hemisphere and deflects it to the right. In the Southern Hemisphere, the force is to the left. This force is responsible for the deflection of winds and ocean currents, and it is why hurricanes and other large-scale atmospheric systems rotate in a counterclockwise direction in the Northern Hemisphere and clockwise in the Southern Hemisphere.

In his book "Movements of Fluids" (1839), Ferrel discussed the Coriolis force in detail and showed how it affects the movement of air and water. He demonstrated that the Coriolis force is the result of the earth's rotation and that it is responsible for the deflection of winds and ocean currents. Ferrel's work laid the foundation for modern meteorology and continues to influence the field today.
A popular exposition of this and other results of Ferrel’s work is given by Archibald in Nature (May 4, 1882), and still better in Ferrel’s own book Nature and Language of the Winds (New York, 1887). The charts of mean annual pressure, temperature and wind above referred to show certain broad features that embrace the whole system of atmospheric circulation, viz., the low pressures at the equator, the high pressures over the earth, the trade winds below and the anti-trades above, with comparative calms under the belts of equatorial low pressure and tropical high pressure. The first effort of the mathematician was to explain how these circulations came to be so organized and how each one of them may be devised a system of general circulation of the wind consistent with the pressures, resistances and densities. But, as we have already said, such a system may be very far from that presented by the real atmosphere, and by little else than the comparative view of the question of the general circulation. The earlier students of storms generally accepted one of two views as to the cause of whirlwinds. They were either (1) formed mechanically by two principal columns of air that met each other, the so-called polar and equatorial currents; or (2) they were due to the ascent of buoyant air while the heavier air flowed in beneath, the whirling motion being communicated by the influence of the rotation of the earth, or by the water resistances on one side than on the other. In order to explain why hurricanes and typhoons exist continuously for many days, or even weeks, it is necessary that there should be a source of energy. There is, therefore, a further and lower current at the centre, and this was supposed to be fully provided for by Espey’s proof of the liberation of latent heat consequent on the formation of cloud and rain. To this latter consideration Abbe in his analysis of the meridional and latitudinal phenomena of the atmosphere, has attributed a very high importance to the condition of the upper surface of the cloud. At this stage of the investigation the whirlwind is but an incident in the general circulation of the atmosphere, but further consideration shows that it ought rather to be considered an intermediate condition of the general circulation, that when temperature gradients and density gradients exceed a certain limit the formation of great whirlwinds is inevitable. Therefore an atmosphere containing several whirlwinds is just as truly a system of atmospheric circulation as is the earth itself. One cannot exist without the other, and the formation of whirlwind is in the other. The formation of the whirlwind, the evolution of latent heat, and even the absorption of heat at the upper surface of the cloud, are connected with the general circulation in a special case. We may therefore consider a system of vortices, which is a system of discontinuous motions, as the most natural solution of the equations of motion—but the mathematical treatment of this form of motion is not yet developed sufficiently, because the discontinuity relates not only to the motion but to the thermal conditions and the interchange of vapour and water.

In 1890 Professor Hann published a careful analysis of the actual temperature conditions prevailing over an extensive area of high pressure in Europe, and showed that the temperatures of the upper strata in both high and low areas, namely, in anti-cyclones and cyclones are often directly contrary to those supposed to prevail by theory. He showed in a study of the distribution of the radiation into the radiation of heat from the dust and moisture of the atmosphere, and Professor Abbe seems to have shown that in areas of high pressure and clear weather a very slow descending motion of air prevails, which is contrary to the hypothesis of the upper strata being the source of the radiation of heat that explains the anomalies of temperature, but the dynamic phenomena still remained — unexplained. On the other hand, von Helmholzt in several memoirs of 1888-1891 showed that waves and billows may be formed in the atmosphere of great extent at the dividing surface between upper and lower strata moving in different directions and with different velocities. Under specific conditions these waves may come to be like the breaking waves of the ocean when driven by the wind. The hypothesis that these aerial breakers correspond to our troughs and ridges and the storms experienced in the lower atmosphere seemed very plausible. These were formed by the juxtaposition of the upper and lower currents of great extent, which themselves represent a large portion of the horizontal circulation between the poles and the equator. It results that if von Helmholzt’s suggestion and Hann’s hypothesis are correct then all general storms must be considered as essentially a part of the general circulation rather than as caused by the vertical circulation over any locality. It must occur to everyone to adopt the intermediate view that on the one hand, the local vertical circulation is the cause, and on the other hand the waves and whirls in the general circulation, mutually contribute toward our storms and fair weather. It only remains to allot to each its proper importance in any special case.

Undoubtedly aerial billows, and the clouds that must frequently accompany them, exist everywhere in the earth’s atmosphere. But in the study of atmospheric phenomena, we should, as always, keep in mind that they are most important under certain conditions. A voyage around the Atlantic Ocean in 1889-1890, made by Professor Abbe, specifically to study cloud phenomena, revealed many remarkable cases, such as the cumulus rolls that extend in a remarkably symmetrical series from the island of Ascension westwards for 100 m. in the south-eastern trades, or the delicate fields of cirro-cumuli that extend from the islands of Santa Lucia and Barbados for 200 m. in the trade winds under favourable conditions. The mixtures and vorticeous motions going on with aerial billows to form these clouds have been interpreted by Brillouin. In the further elucidation of the mechanism of storms Hann showed that this natural study has been greatly helped by the fact that the descent of denser cool dry air is as important as the ascent of warm moist air, and that although the evolution of latent heat within the clouds of a storm may explain the local cloud phenomena, yet the various ocean currents, which include the "hurricane" or "blizzard" that was charted at Washington in November 1871 was at once seen to be a case of the underflow of a thin layer of cold dry air descending from high latitudes above Canada on the eastern coast. The important aspect of centrifugal acceleration added to a moderate baromeric gradient. It was seen that in such grand overturnings the descent of masses displaces the communication bell which has been fixed, and that the mechanics of this process was not clear until the publication by Margules of his memoir Über die Energie der Stürme (Vienna, 1905), which will be referred to hereafter.

Mathematics have, almost without exception, assumed a so-called steady condition in the motion of the atmosphere in order to achieve a successful integration of the general equations of motion. The restrictions within which Helmholtz and others have worked, and the method in which their results are to be accepted, are analysed by Dr E. Herrmann in a memoir of which a translation is published in the bulletin of the American Mathematical Society for June 1896. Of course Herrmann’s own investigation is also based on these restrictions and systematizations of mathematical theories of disturbing forces and of viscosity and friction, a homogeneous elliptoidal surface, and a uniform initial temperature and rate of rotation. Conversely, the atmosphere must be considered to be set in a state of equilibrium by separating the initial static equilibrium be disturbed by introducing a different distribution of temperature, viz., one that varies with altitude and latitude, but is uniform in longitude along any circle of latitude, and the first question is whether the atmosphere can settle down to a new state of static equilibrium. Herrmann shows that in general it cannot do so, but that the new state and the future states can only be those of motion and dynamic equilibrium. If, however, there is no disturbing influence the force of the atmosphere at the state of equilibrium relative to the earth can occur, namely, when the new temperatures are so distributed in the atmosphere as to satisfy the equation

$$\int_{A}^{D} \rho \, dV = M,$$

in addition to the ordinary equations of elasticity, inertia and continuity previously given, and to those representing the boundary conditions. $M$ being the total amount of inertia of the atmosphere relative to the axis of rotation. In general, the movements in the atmosphere must consist not only of an interchange between the limits within which the results are to be accepted, and there must therefore be a different rate of diurnal rotation at each of the limits. The second step in this inquiry is, Can these movements become perfectly steady with this unvarying or steady distribution of atmosphere. In other words, are the movements be so adjusted to each other that each shall remain invariable within any given zone of latitude? The reply to this is, that if they are to become thus adjusted they must satisfy a certain equation with respect to their distribution of temperature, moisture, and the statical or the dynamic state of the atmosphere. Generally speaking, it is impossible for the atmosphere to change its condition completely to a state of steady equilibrium, and this is also true of stationary currents cannot exist if there be any north or south component. Apart from the fact that Herrmann assumes no friction, it would seem that he has proved that steady motions and statical states cannot exist in the atmosphere over a homogeneous spherical surface, and presumably the same result would follow from a rotating globe for the irregular surface of the actual globe. The motions of the real atmosphere must therefore consist of irregular oscillations of little extent, and the pressure systems are imposed upon more uniform, regular progressions, but never repeating themselves. Consequently, the conclusions deduced by those who assume that steady conditions are possible must depart or lose their foundation. The cause of the atmospheric impression that the belt of low pressure at the equator and the low areas at the poles and the high pressures under the tropics are maintained is the result of the interplay of the"super-annular" and "annular" conditions if we had an ideal smooth globe; but Herrmann’s researches show that the unsteadiness observed to attach to those areas under existing conditions would also attach to them under ideal conditions. It is therefore entirely misleading to take any one of the oscillations by taking annual averages, obtain an ideal annual distribution of pressure, temperature and wind that does not represent any specific dynamic problem. The averages represent what is considered proper geometry, but the value of the results depends on the basis of the dynamic point of view and have no logical mechanical connexion with each other.
in the heat received from the sun; for instance, what variation in the earth's atmosphere corresponds to the periodic variations of the solar spots. The general current of Helmholtz's investigations shows that no periodic change in the earth's atmosphere can be observed without the influence of the sun, and some periodic influence outside of the atmosphere. On the other hand, it is barely possible that wave and vortex phenomena on the sun's surface may have the same periodicities as regular phenomena in the earth's atmosphere. But there may be a parallelism without any direct connection between the two.

An important paper on the application of hydrodynamics to the atmosphere is that by Professor V. Bjerknes, of Stockholm, published in an English translation in the U.S. Monthly Weather Review, Oct. 1900 ("On the Dynamic Principle of Circulatory Movements in the Atmosphere"). In this memoir Bjerknes applies the precepts of terrestrial hydrodynamics, specifically those of Helmholtz, Kelvin and Silberstein, and others of his own invention to the atmospheric circulation. He simplifies the hydrodynamic concepts by dealing with density directly instead of temperature and pressure, and uses charts of isobars, isotherms, or lines of equal density, very much as was proposed by Abbe in 1889 in his Preparatory Studies, where he utilized lines of equal buoyancy or "isobaths," and such as Ellholm published in 1891 as isodenses, and which were each of three movable axes passing through the center of the earth. The apparent success with which the hydrodynamical method has thus been made practicable to apply hydrodynamic principles in a simple manner without the necessity of analytically integrating the equations, at least for many ordinary cases. He also gives an important criticism of the judge's judgment of the agreement between the physical theory, according to which cyclones are perpetually rotating in the opposite direction to the Coriolis, and the mechanical theory, according to which they are simply carried along in the general atmospheric current. Bjerknes's paper is illustrated by another one due to Mr. Sandström, of Stockholm, who has also made many observations in the United States.

The further development of Bjerknes's methods promises a decided advance in theoretical and practical meteorology. His profound lectures at Columbia University in New York and in Chicago have already exerted an influence throughout the United States. Among the applications of the methods of analysis given in detail in Bjerknes's Vorlesungen i der Meteorologien (Leipzig, 1900, ii. 1901), and in his Recherches sur le champ de force hydrodynamiques (Stockholm, Acta Mathematica, Oct. 1905), are the application of the atmospheric condition at any moment by a series of isodens surfaces intersecting potential surfaces of equal gravity and thus forming a continuous network of isobars and isotherms. The method is analogous to the intrinsic magnetic or hydrodynamic field according to the interpretation assigned to the isobars—in either case the atmospheric processes are identical. The analogies or homologies of these three sets of processes are on record, and the reason for the greater elucidation or illustration of those of the two other fields. This is the outcome of the study of such analogies begun by Euler, Helmholtz, Hoppe, and extensively furthered by Maxwell and Kelvin, but especially by C. A. Bjerknes.

which have been slightly rectified by Dr. G. H. Ling, Am. Jour. Math. (1908). In the application of Bjerknes's methods to the daily weather map Sandström draws special maps to represent the solenoids and the forces. Barometric pressures are reduced up to about the height of the layer of the earth's atmosphere that may be a parallelism without any direct connexion between the two.

The Diurnal and Semi-diurnal Periodicities in Barometric Pressure.

For a long time attempts were made to explain the periodic variations of the barometer by a consideration of static conditions, without success. The most successful attempt was that of Bjerknes, who published a mathematical derivation of the periodic variations of the barometer in 1898, of the atmosphere, is a question of aerodynamics. A most extensive series of researches into the character of the phenomena from an observational point of view has been made by Hann, who gave a valuable new formula for diurnal and semi-diurnal periodicities (1898, Trans. R. H. Scott in the Quart. Jour. Roy. Met. Soc. (Jan. 1899) (see also an important addition by Hann and Trubert in the Met. Zeit. 1899.) and the summary of his results as given in his On the nature and the cause of the diurnal and semi-diurnal periodicities. Three regular periodic variations are established by observation, viz. the diurnal, semi-diurnal and ter-diurnal. On the higher mountains these variations change their character with latitude. (1) At the equator the diurnal variation is represented by a sine curve (+α, +β, +γ) the amplitude of the sun.

The amplitude of this variation is greatest in equatorial regions, and is expressed by the formula A = (0.988 · 0.573 · sin α) as given by Hann, or A = (0.927 · 0.545 · sin α) as given by R. H. Scott. The periodicity of the phase angle is 160° and at 50° N. it is 142°, and between these limits it may be the same over the whole globe, so that the phase does not depend clearly upon the hour angle of the sun or on the local time. The amplitudes appear to depend on the excess of land in the northern hemisphere as compared with water and cloud in the southern, the same being greater at the equator and least at the arctic. Hann suggests that the semi-diurnal periodicity of the sea may be greater in the southern hemisphere when it is in antiparallel, owing to the preponderance of land in the north and water in the south. The diurnal periodicity is accounted for by the formula of the moon or 0.04 mm. sin (35° + 32). The phase angle is sensibly the same everywhere, and the amplitude varies slightly with the latitude. Both phase and amplitude have a pronounced annual variation, the maximum amplitude occurring in January in the northern hemisphere, and in July in the southern.

The physics of the atmosphere has not yet been explored so extensively as to explain all the known periodic barometric variations, but neither have we as yet any necessity for appealing to some unknown cosmic action as a possible cause of their existence. The action of the solar heat upon the illuminated hemisphere, and the consequent evaporation, is sufficient to explain the barometric periods. The variations of sunshine and cloud must inevitably produce periodic variations of temperature, moisture, pressure and motion, whose exact laws we have not as yet fathomed. Among the many methods of studying the influence of the sun and the greatest difficulty we have in connecting the barometric variations the most important is of all the so-called tidal wave of pressure due to temperature. Laplace applied his investigations on the tides to the gravitational tide of the ocean, and extended the results to the solar and lunar tides of the atmosphere he was able to show that they must be inappreciable, unless, indeed, certain remarkable relations existed between the circumference of the earth and the depth of the atmosphere. As the relation, however, is not quite as we should expect it to be, and the gravitational tides, both diurnal and semi-diurnal, cannot exceed a few thousandths of an inch of barometric pressure. On the other hand, the same process of mathematical reasoning enables us to investigate the action of the sun's heat in producing a wave of pressure that has been called a tides, due to the expansion of the lower layer of air on the illuminated half of the globe. The laws that must govern these tides have been investigated by Kelvin, Rayleigh (Phil.
The mathematical treatment of the subject began with the memoir of Kelvin on convective equilibrium (see Trans. Manchester Phil. Soc., 1861). The most convenient method of dealing approximately with the problem is graphical and numerical rather than analytical, and it is on this subject that we will work. Kelvin published his diagram for adiabatic changes in the atmosphere in the Met. Zeit. in 1884. He considers the adiabatic changes of a kilogram of mixed air and aqueous vapour, the proportional weights of each being \( \lambda \) and 1 respectively. The diagram is used to represent the conditions of the atmosphere and the curves for the different stages are laid down with the aid of Kelvin's tables for the pressure and temperature of saturated air at any height in the atmosphere. The usual method is to lay down a curve for each stage and then to interpolate between them. This is done by a graphical method which involves the use of a logarithmic scale for the pressure and a linear scale for the temperature. The interpolation is made by drawing a straight line between the points corresponding to the pressures and temperatures of the two adjacent stages.

The diagram is then used to illustrate the processes of adiabatic change in the atmosphere and to show the effects of these processes on the temperature and pressure of the air. The diagram is also used to illustrate the effects of changes in the temperature and pressure of the air on the conditions of the atmosphere and to show the effects of these changes on the temperature and pressure of the air.

The diagram is used to illustrate the processes of adiabatic change in the atmosphere and to show the effects of these processes on the temperature and pressure of the air.
of snow left within the clouds must be very small, and the cloud has the delicate appearance peculiar to cirrus. Hertz's original diagram is quite covered by these systems of \( \alpha, \beta, \gamma \) and \( \delta \) lines, and the moist lines. The lines show the density of the moist air at different altitudes. The theory of the process, however, which Hertz published in 1900, is reprinted in the second volume of Abbe's Mechanics of the Earth's Atmosphere, and its arrangements help to solve many problems suggested by the recent progress of aerial research.

In this treatment of the subject only illustrative diagrams are published, because the different conclusions drawn to scale, are necessarily too large and detailed. He presents graphically the exact explanation of the cooling by expansion, the loss of both mass and heat by the rainfall and snowfall, and the warming of the remaining air. If it descends as fohn winds in Switzerland, and winds in Montana. Even in the neighborhood of a storm over the land, the moist air, in front of the rain, after being carried up to the rain or snow stage, flows away on the upper wind until it passes through the lower wind. When the temperature of the upper wind is lower than that of the lower wind, there is a point on the opposite side of the central low pressure. In order to have a convenient term expressive of the fact that two masses of air in different portions of the atmosphere having different pressures, temperatures, etc., may be in equilibrium with each other, it also necessarily attain the same temperature. Von Bezold introduced the expression "potential temperature," and devised a simple diagram by which the potential temperature may be determined for any mass of air whose constant pressure, temperature and moist are known. In an ascending mass of air, from the beginning of the condensation onwards, the potential temperature steadily increases by reason of the loss of moisture, but in a descending mass of air it remains constant throughout the process of condensation. The difference between the potential temperature at any point of its previous path. In general the potential temperatures of the upper strata of the atmosphere are higher than those of the lower. In general the so-called vertical temperature gradient is smaller on the land than on the sea.

The latter latter case is 0.993° C. per hundred metres for the dry stage, but the actual atmospheric observations give about 0.6°. Apparently this difference represents primarily the latent heat transfer. On account of the relative insensitivity of the temperature to the specific humidity, the temperature is often determined by means of the relative humidity and the temperature is determined by means of the specific humidity. However, the temperature relates to the formation of rain, and further details have been considered by von Bezold. The practical tables contained in Professor Bigelow's report on clouds, and those of Neuhoff as arranged for the use of meteorological observation, are of great value, and to the train of thought, complete our methods of studying this subject.

A most important application of the views of von Bezold, Hertz and Helmholtz was published by Brillouin in 1898. This was that a train of cold fronts, just as a train of warm fronts, is not due either to the general distribution of heat or to local influences exclusively, but in part to each, and just as we have learned that the temperature of the air is not due either to radiation and absorption or to the cooling by water or of the air, so we will discover that the phenomena of rain and cloud the precipitation is not always due to the cooling by mixture, or to the cooling by expansion, or to radiation, but is general a complex result of all. The effect of the evaporation and condensation can be treated by elementary geometrical methods, by means cold currents has always been understood in a general way, but was first brought to prominence by Espsy in 1838, and perhaps equally forcibly by Faye in 1875. Helmholtz, in his memoirs on billows in the atmosphere, showed how the continuous movement of the atmosphere causes the earth to be a perfect sphere, and that the rotation of our globe, assumes a much more complicated character than that which obtains when the air has no horizontal but only a vertical motion. We know in a general manner, that the earth is a sphere, and the heat distribution is uniform or parallel. But it is evident that one can learn much as to the condition of permanence or destruction of annullae zones having uniform and parallel movements. Thus simplified, the question can be treated by elementary geometrical methods, by means of which we at once rediscover and complete the results given by Brillouin for zones of clear air and discover a whole series of new results for zones of cloudy air." Among Brillouin's results are the following theorems:

A. If the atmosphere be divided into narrow zonal stages, each having the same potential temperature, it is found that there will be a narrow zone of constant potential temperature, that extends over a narrow zone of latitude, and if each is within itself in convective equilibrium so that the surfaces of equal pressure shall be surfaces of revolution around the axis of rotation, then within such complete ring it is found that any point within the ring will be subject to a constant force directed towards the nearer pole of the globe, the intensity of the force will vary in inverse ratio of the square of the distance from the axis of rotation, and that constant is such that if upon, the air will not move like a rotating solid, but will have a variable angular velocity, smaller far the nearer the axis is.

B. The surfaces of equal pressure are more concave towards the centre than is the surface of the globe itself, and they are tangent to the latter only along the parallel where calms prevail.

C. The gaseous atmosphere is a frictionless globe divided itself into concentric rings whose angular movements increase as we pass from the polar region towards the equatorial ring; the central globe rotates much faster than the equatorial atmospheric ring.

D. The surface of separation between two contiguous concentric rings must be such that the atmospheric pressure shall have the same value as one approaches this surface from either direction, and the surface of separation is stable if the differences of pressure in any parts of this surface must be determined by the position of equilibrium. As the distribution of pressure along a line parallel to the axis of rotation is independent of the velocity of rotation, the ordinary condition of stability, viz. that the gas of which the lower ring is composed is lighter than the gas of which the upper ring is composed, applies for this line. In general, any inclination of the surface of separation to the horizon amounting to 10° must be associated with very small differences of density and large differences of velocity; in practice, this is true for all inclinations.

E. If the surfaces of equal pressure or isobars are nearly horizontal, as in ordinary cases, the calculations are comparatively easy to make. Let the inclination of the isobaric surface ascending towards the pole be denoted by \( \alpha \), the distance measured in the direction of the attraction of gravity; then the angle of inclination of the isobaric surface is given by the equation

\[
\tan \phi = -\frac{h_i - h_i \sin \lambda}{h_i \cos \lambda}
\]

where \( \lambda \) is the complement of the angle between the direction of gravity and the line drawn to the pole, or the axis of rotation of the earth. The surface of separation is that over which the pressure is constant and equal to that of the middle surface. If \( h \) be the distance measured with a vertical plane only when the densities and velocities in the two layers have certain specific relations to each other. It can never be between the isobaric surfaces that Brillouin designates as 1 and 2. In other words, the surfaces of separation of the three different of one if one is limited by the other two are indefinite, must all run together at a common point or edge, very much as in the problem of the equilibrium of thin films.

F. When the contiguous zones are cloudless the mixtures take place under the influence of free convection. In stable conditions, the cloudless mixture ascends on the polar side when the west wind which prevails on the equatorial side of the surface of separation is warmer, but descends between the pole and the equatorial side of the surface of separation when the west wind which prevails on the equatorial side of the surface of separation is colder. The mixtures of cloudless air rapidly occupy the whole height of the two layers that are mixing. When they form along a surface that becomes unstable the wind which is parallel to this surface will become extremely conical. This whirlwind may be limited as to height when the two contiguous zones that are mixing are surmounted by a third clear or cloudy layer which intersects the other two and whose lower surface is stable. (Brillouin suggests that this corresponds to the formation of water-spouts and tornadoes.)

G. When the contiguous zones are cloudy and the mixtures produce decuded condensations, and sometimes even precipitation, much may be learned as to the condition of the initial stages of the formation of convection currents. Analytical methods permit us to resolve complex questions only for limited areas in longitude and for contiguous zones of high and low pressure, but not for large areas. At the equator, whatever may be the difference of
temperature, a mixture accompanied by condensation always descends when the surface of separation is unstable; moreover, the adiabatic compression rapidly evaporates the mixture.

In the last three chapters of his memoir, Brillouin applies these principles to a variety of mixtures due to the pressure of one current of air against another. Fig. 11, prepared for the U.S. Monthly Weather Review (Oct., 1897), gives five of the cases elucidated by Brillouin. In each of these the left-hand side of diagram is the polar side, the air being cold above and the wind from the east, while the right-hand side is the equatorial side, the air being warm above and the wind from the west. The reader will see that in each case, depending on the relative temperature and winds, layers of cloud are formed of marked individuality. As none of these clouds appear in the International Cloud Atlas or the various systems of notation for clouds, one is all the more impressed with the importance of their study and the success with which Brillouin has opened up the way for future investigators. "We have no longer to do with personal and local experience, but with a methodical description of a small number of characteristics easy to comprehend and applicable at every locality throughout the globe."

From a thermodynamic point of view the most important study is that published by Margules, Uebcr die Energie der Stformen (Vienna, 1905). This work considers only the total energy and its adiabatic transformations within a mass of air constituting a closed system. Truly adiabatic changes in closed systems do not occur within any special portion of the earth's atmosphere, neither can our entire atmosphere be considered as one such system—but Margules' results are approximately applicable to many observed cases and complete the demonstration of the general truth that we must not confine our studies to the simpler cases treated by Esy, Rey, Sohnke, Peslin, Ferrel, Most. All imaginable combinations of condensation in the atmosphere, and a method must be found to treat the whole subject comprehensively and rigorously.

The three equations of energy on which Margules bases his work are:

\[ R + (K + P) + 6A = \delta l - 6A - Q \]
\[ R + (K + P) + 6l = Q \]

where \( R \) = energy lost by friction or converted into heat; \( K \) = kinetic energy due to velocity of moving masses; \( P \) = potential energy due to location and gravity and pressure heat; \( A \) = work done by internal forces when air is expanding or contracting; \( l \) = internal energy due to the existing pressure and temperature; \( Q \) = quantity of heat or energy added or lost during any operation and which is zero during adiabatic processes only.

These equations are applied to cases in which masses of air of different temperatures and moistures are superposed and then left free to assume stable equilibrium. It results in every case that there is no free energy developed. Any condensation of moisture by expansion is counterbalanced by redistribution of potential energy and by the work done in the interchange of locations. The idea that barometric pressure gradients make the storm-winds is seen to be erroneous and the primary importance of gravity gradients is brought to light. This is the only important potential energy of position and in the velocity of ascent and descent, although these are generally lost sight of owing to the great horizontal and small vertical dimensions of the storm areas. The horizontal distribution of pressure must be to be a forced transition within the storm areas at the boundary surface of the earth, by reason of which a small part of the mass of air acquires a greater velocity than it could by ascending in the coldest or sinking in the warmest part of the storm areas. But now we come to problems that cannot be solved by considering the energy only."

This latter quotation emphasizes the necessity of returning to the equations of motion. The thermodynamics and hydrodynamics of the atmosphere must be studied in concert and no longer be separated. Apparently we may expect this next step to be taken in the above-mentioned work promised by V. Bjerknes, but meanwhile Professor F. H. Bigelow has successfully attacked some features of the problem in his "Studies on the Thermodynamics of the Atmosphere" (Monthly Weather Review, Jan.-Dec. 1906). In ch. iii. of his studies (Monthly Weather Review, March 1906) Bigelow establishes a thermodynamic formula applicable to non-adiabatic processes by introducing a factor \( r \) so that the pressure \( P \) and absolute temperature \( T \) are connected by the formula

\[ P = \frac{r^T - 1}{T} \]

In our fig. 1 above given, Cortier has assumed \( r = 1 - 2 \), but as the values have now been computed for all altitudes from the observations given by balloons and kites, and have a very general importance and interest, we copy them from Bigelow's Table 16 as below:

storms (Monthly Weather Review, November 1907–March 1909) with considerable success.

We have thus passed in review the steady progress of mathematical physicists in their efforts to unravel the complex dynamics of our atmosphere. The profound importance of this subject to geophysics in general, to weather forecasts, and to the whole civilized world, stimulates diligent effort to overcome the inherent difficulties of the problems. An elaborate system of study and laboratory experimentation leading up to research in meteorology has been devised by Cleveland Abbe, culminating in experiments on models of the atmosphere as a whole by which to elucidate both the local and the general circulation on globes whose orography and distribution of land and water is as irregular as that of the earth. The Formation of Rain.—Not only has dynamic meteorology made the progress delineated in the previous sections, but one of the most important questions in molecular physics is in process of being collaborated. The study of the phenomenon of condensation and the formation of clouds in their relation to daily meteorological work began with the appointment of Dr Carl Barus in 1891 as physicist to the U.S. Weather Bureau, and his work has been laboriously continued and extended in his laboratory at Providence, Rhode Island. The formation of rain, from a physical point of view,
is the immediate step in the formation of cloud. The cloud consists, like fog, of extremely small particles, so light that they float indefinitely in the air; rain and snow represent those particles that have grown to be definitely and heavy enough to be long sustained by their mutual attraction or by the attraction of the earth. The density of the air, being greater than the ascending component of the air in which they float. The process by which larger drops are formed out of the lighter particles that constitute a cloud has not yet been satisfactorily explained. It is probable that either one of several processes contributes to bring about the condensation of the water vapor into rain drops, rather than that these processes work together. The following paragraphs represent the hypotheses that have marked the gradual progress of our knowledge:

A. Cloud particles may be driven together by the motions imparted to them by inertia, or may be produced by the impact of minute particles, which, as they descend more rapidly, overtake the smaller ones and grow into raindrops.

B. The particles on the upper boundary of a cloud may at night-time unite, to the formation of larger masses, and—decidedly more distant than their neighbors below them, either by radiation or by mixture; then the air in their immediate vicinity becomes correspondingly cold, the particles and their envelopes of cold air sink more rapidly, overtaking, and therefore condensing, the larger droplets.

C. Some cloud particles may be supposed to be electrified positively and negatively, causing them to attract each other and run together into larger ones, or, again, some may be neutral and the others charged, which may also attract each other.

D. When any violent agitation of the air, such as the sound waves due to thunder, or cannonading, or other explosions, sets the particles in motion, they may be driven together until brought into contact, and then coalesce into raindrops.

E. The air—or, properly speaking, the vapour—between cloudy particles—that is to say, within fog or cloud, is generally in a state of supersaturation; but if it is steadily rising to higher altitudes, thereby expanding and cooling, the air must become more positively charged as it expands, and, it is suggested, the clouds may then be drained of their electric charge, and be at a lower potential than before.

F. However plausible the preceding five hypotheses have seemed to be, none has ever yet observed precipitation actually formed by these processes. The laborious observations of C. T. R. Wilson of Cambridge, England, probably give us our first correct idea as to the molecular processes involved in the coalescence of drops. A hot drop of water floating in the air, no matter what may be its original size, becomes postulated to become negative, the droplet to which it is attracted is thus rendered positive, the latter could only occur when the air is cooled to a much greater extent than in the case of the air still negative; in fact, dustless air required to produce the same amount of charge of one positive drop

IV. COSMICAL METEOROLOGY

Under this title have been included all possible, plausible, or imaginary relations between the earth's atmosphere and interplanetary space, or the heavenly bodies. The diffusion to and fro at the outer limit of the atmosphere, the bombardment of rays from the sun, the explosion of auroral lights and of magnetic storms, the influence of shooting stars and comet tails, the relation of the zodiacal light and the Gengeschein to the atmosphere, the parallelisms between terrestrial phenomena and the variations of the solar spots and protuberances, the origin of long or short climatic periods, the cause of special widespread cold days, the existence of lunar or solar tides, the influence of slow changes in the earth's orbit or the earth's axis of rotation—all are grouped under cosmical meteorology.

But, in the writer's judgment these matters, while curious and interesting, have no appreciable bearing on the current important questions of atmospheric mechanics. There seem to be many widespread delusions and mistakes in regard to these problems, analogous to the popular errors in regard to astrology, and it is hardly necessary to do more than allude to them here. The leading meteorologists have relegated such questions to the care of theoretical astronomers and physicists until we are better equipped by our knowledge of our atmosphere, and then a better definition of the immediate physical mechanism, and to the study of the various internal mechanism afford us a bewildering maze of problems such that so long as we are unsolved it would be folly to spend time on those.

V. METEOROLOGICAL ORGANIZATIONS

During the latter half of the 19th century the prosecution of work in meteorology gradually passed out of the hands of individuals into the control of large national organizations. This was the natural result of the discovery that, by the spread of the electric telegraph and cable, it was possible to compile daily weather-maps for large portions of the globe and to make predictions of the weather and the storms for a day or two in advance, with sufficient accuracy to be of the greatest importance to the material interests of civilized nations.

The development of wireless telegraphy since 1900 has even made it possible for isolated ships at sea to exchange weather telegrams, compile daily maps and study surrounding storms. One by one every civilized nation has established either a weather bureau or a meteorological office, or a bureau of hydrography and marine meteorology, or an elaborate establishment for making observations according to its special interests demanded. These governmental bureaus usually pursue both climatological and theoretical meteorology in addition to their daily practical studies.
work of telegraphy, forecasting, and publication of charts. Although, of course, in most cases, the so-called practical work absorbs the greater part of the labour and the funds, yet everywhere it is recognized that research and the development of a correct theory of the motions of the atmosphere are essential to any important progress in the art of forecasting. Among other important general works in which the official weather bureaus have united, we may enumerate the International Meteorological Congresses, of which the first was held in 1853 at Brussels, the second in 1873 at Vienna, and others more frequently since that date; the establishment of an International Committee, to which questions of general interest are referred; the organization of a systematic exploration of the polar regions in the years 1882 and 1883; the general extension of the meteorological services to include terrestrial magnetism as an essential part of the physics of the globe; the systematic exploration of the upper atmosphere by means of kites and balloons; and the universal co-operation with the U.S. Weather Bureau in the contribution of simultaneous data for its international bulletin and its daily map of the whole northern hemisphere. The hydrographic offices and marine bureaus of the principal commercial nations have united so far as practicable in the daily charting of the weather, but have especially developed the study of the climatology of the ocean, not only along the lines laid down by Maury and the Brussels Conference of 1853, but also with particular reference to the tracks of storm centres and the laws of storms on the ocean. The condition of these governmental organizations was discussed in the annual address of the Hon. F. Campbell Bayard, delivered before the Royal Meteorological Society of London in January 1890, and in the text accompanying Bartholomew's Physical Atlas, vol. iii.

The development of meteorology, in both its scientific and its practical aspects, is intimately dependent upon the progress of our knowledge of physics, and its study offers innumerable problems that can be solved only by proper combinations of mathematical theory and laboratory experimentation. The professors in colleges and universities who have hitherto lectured on this subject have not failed to develop some features of dynamic meteorology, although most of their attention has been given to climatology. In fact, many of them have been engaged in the study of general problems in molecular physics, and could give meteorology only a small part of their attention. The early textbooks on meteorology were frequently mere chapters or sections of general treatises on physics or chemistry. The few prominent early cases of university professorships devoted to meteorology are those of the eminent Professor Heinrich Wilhelm Dove at Berlin, Professor Adolphe Quetelet at Brussels and Professor Ludwig Friedrich Kaemtz at Halle and Dorpat. In modern times we may point to Professor Wilhelm von Bezold and George Hellmann at Berlin, Professor Julius Hann at Vienna and Graz, Professor Josef Maria-Perner at Linz and Vienna, Professor Alexander Woieok at St Petersburg, Professors Hugo Hildebrandt-Hildebrandsson at Upsala, Henrik Mohr at Christiania, Adolph A. Brown at New Haven, and R. Q. Ward at Cambridge, Massachusetts, Alfred Angot and Marcel Brillouin at Paris, Hugo Hergesell at Strassburg, Arthur Schuster at Manchester, Peter Polis at Bonn, and Richard Börnstein at the School of Agriculture in Berlin. With these exceptions the great universities of the world have as yet given but little special encouragement to meteorology; it has even been stated that there is no great demand for higher education on the subject. On the other hand, the existence of thousands of voluntary observers, the profound interest in the weather actually taken by every individual, and the numerous schemes for utilizing our very limited knowledge of the subject through the activities of the large weather bureaus of the world demonstrate that there is a demand for knowledge perhaps even higher than the universities can offer. It would be very creditable to a nation or to a wealthy patron of science if there should be established meteorological laboratories in connexion with important universities, at which not only instruction but especially investigation might be pursued, as is done at the magnificent astronomical observatories that are so numerous throughout the world. Every atmospheric phenomenon can be materially elucidated by exact laboratory experiments and measurements. theory can be confronted with facts; and the student can become an original investigator in meteorology.

The great difficulties inherent to meteorology should stimulate the devotion of the highest talent to the progress of this branch of science. The practical value of weather predictions justifies the expenditure of money and labour in order to improve them in every detail.

BIBLIOGRAPHY.—Those who desire recent additions to our knowledge should consult first Hann's Lehrbuch der Meteorologie (2nd ed., 1883); and for a long time after that, the Meteorologische Zeitschrift (Berlin and Vienna, 1866 to date). The Atlas of Meteorology (Bartholomew, 1900), the Quarterly Journal of the Royal Meteorological Society (London) and the Annalen der Physik und der Chemie (Berlin), are full of rich matter, and abound with references to current literature. The Physical Review Science Abstracts and the Fortschriften der Physik contain short notices of all important memoirs and will serve to direct the student's attention toward any special topic that may interest him. (C. A.)

METER, ELECTRIC. In the public supply of electric energy for lighting and power it is necessary to provide for the measurement of the electric energy or quantity by devices which are called electric meters. Those in use may be classified in several ways: (i) according to the kind of electric supply they are fitted to measure, e.g. whether continuous current or alternating current, and if the latter, whether monophasic or polyphase; (ii) according to whether they record intermittently or continuously; (iii) according to the principle of their action, whether mechanical or electrolytic; (iv) according to the nature of the measurement, whether quantity or energy meters. The last subdivision is fundamental. Meters intended to measure electric energy (which is really the subject of the sale and purchase) are called Joule meters, or generally watt-hours meters. Meters intended to measure electric quantity are called coulomb meters and also ampere-hour meters; they are employed for the measurement of public electric supply on the assumption that the electromotive force or pressure is constant. Most of the practical meters in use at the present time may be classified under the following five heads: electrolytic meters, motor meters, clock meters, intermittent registering meters and induction meters.

Electrolytic Meters are exclusively ampere-hour meters, measuring electric energy directly and electric energy only indirectly, on the assumption that the pressure of the supply is constant. The first electrolytic meters were invented by Sprague and were described by St. George Lane-Fox. He was followed by F. J. Sprague and T. A. Edison, the last-named inventor elaborating a type of meter which he employed in connexion with his system of electric lighting. Sprague's work was further developed by Sprague and his co-inventor, T. J. Havens, and the last-named in particular in the construction of the London Electric Lighting Company's meters. In the manufacture of the London Electric Lighting Company's meters, it was found, however, that certain defects, such as the imperfect stability of the electrolyte, the circumstance that the electrical resistance of the plate was not constant, and the absence of a simple method of measuring the quantity of electric energy which had been passed through the meter, the electrolyte was discarded in many cases in favour of the mechanical method of registering the quantity by means of a pointer on a dial. In the construction of the London Electric Lighting Company's meters, a direct connexion was made between the plates and the circuit being measured, the plates being connected to the circuit by means of shunt conductors or 'lugs.' These conductors were arranged so that the cells could be weighed at inspection and the quantity of energy measured by means of a balance without electrical connexion with the circuit being measured. The shunted voltameter was then inserted in series with the electrical supply mains leading to the house or building taking electric energy, and the current which passed dissolved the zinc from one plate and deposited it on the other, so that after a certain interval of time had elapsed the altered weight of the plates enabled the quantity of electricity to be determined. As a result of the invention of an electric current of one ampere, flowing for one hour, removes 1,213 grammes of zinc from a solution of sulphate of zinc. Hence the quantity in amperes and hours could be measured by weighing the altered weight of the plates, and the accuracy of the method was increased with a rise of temperature by the same amount that the electrolyte decreased. Owing to the cost and trouble of weighing a large number of zinc plates, this type of meter fell into disuse.
A more modern type of electrolytic meter is that due to C. O. Bastian. The whole current supplied to the house flows through an electrolytic cell consisting of a glass tube containing two platinum electrodes; the electrolyte is dilute sulphuric acid covered with a thin layer of oil to prevent evaporation. As the current flows it decomposes the water of the electrolyte, and the hydrogen of which escape. The quantity of electricity which is passed is estimated by the diminution in the volume of the liquid. A third electrolytic meter of the shunted voltmeter type is that of A. W. Dietzgen. The movement is of the permanent iron core which is completely enclosed in a glass tube of a particular form, having a mercury anode and a platinum or carbon cathode. The current is determined by measuring the volume of the mercury delivered through the tube. So arranged as to indicate the consumption in Board-of-Trade units (1 Board-of-Trade unit = 1000 watt-hours). A modification of the above device with some mechanical improvements has been described by S. Evershed.

Motor Meters.—Amongst motor meters one well-known type belonging to the amperre-hour species is that of S. Z. Ferranti, who introduced the instrument about 1887. In this the current passes through a permanent iron core of which is a flat disk-like cavity containing mercury, the sides of the cavity being stamped with grooves. The thin disk of mercury is therefore traversed perpendicularly by lines of magnetic force when the magnet is excited. The current, being measured, is passed through the coils of the electromagnet, the mercury disk at the centre, flows through it radially in all directions, and emerges at the periphery. The mass of mercury is thus set in motion owing to the tendency of a conductor conveying an electric current to move in the field of force it generates. In these small magnets it becomes in fact the armature of a simple form of dynamo, and rotates with a speed which increases with the strength of the current. The roughness of the surface of the cavity serves to retard it. The rotation is thus determined by the electromotive force induced in a small vanadium of platinum immersed in it, the shaft of this vanadium being connected by an endless screw with a counting mechanism. The core of the electromagnet is worked at a point far below magnetic saturation, and hence it is very sensitive and free from hysteresis. In these instruments it rotates in the square of the current, and the resistance offered to the rotating mercury by the field due to the sides of the cavity is nearly proportional to the square of the speed. It follows that the number of revolutions of the armature is nearly equal to the square of the quantity of electricity which is passed through the meter. In order to overcome the friction of the counting train, Ferranti ingeniously gave to the core of the electromagnet a certain amount of permanent magnetism. Another form of this instrument, worked on a somewhat similar principle, is that of Chamberlain and Hookham. In this form the core of the instrument consists of a single horseshoe permanent magnet formed of tungsten-steel having a strong and constant distribution of magnetic field. The faces of the magnet are made in one field parallel to each other. In one of these a copper disk, called the meter-disk, revolves, and in the other a copper armature disk. The latter is slit radially, and the magnetic field is so arranged that it rotates each half of the disk opposite directions. The armature is immersed in the magnetic field in such a manner that the lines of force pass from the vessel and the armature, except at the ends of the copper strips. The current to be measured passes transversely across the disk and causes it to revolve in the magnetic field; at the same time the friction of the train is reduced. The action caused by local or eddy currents produced in the disk has consequently on which runs between the poles of permanent magnets that create eddy currents in it and therefore exert a retarding force. In proximity to the upper side of the disk is placed a coil of wire having an iron core, which is so arranged that the eddy currents induced in the minimal section of the supply mains cause this core to revolve under the influence of the induced electromotive force of the circuit to be measured; hence if the main current is in step with the potential difference of the terminals of the supply mains, which is the case when the meter is correctly connected, the effect of the shunt core will be due to the shunt coil only. Since the eddy currents induced in the disk are 90 degrees in phase behind the inducing field, the eddy currents produced by the shunt core are out of phase with those due to the shunt, and hence the disk is driven round by the revolution due to the action of the shunt coil upon the induced currents in the disk. Hence the disk will be accelerated until the driving force due to the shunt core is equal to the retarding force due to the induced currents created in the disk by the permanent magnets. When this is the case, the number of revolutions of the meter in a given time is a measure of the watt-hours or energy which is passed through the meter. The counting mechanism and dial may be arranged as in the case of this armature type. The meter is made up also in a form suitable for use with two or three fixed electric currents. (See ELECTROMETERS.)

Requirements of a good House Meter.—A gas meter which has an error of 5% or more, or 3% or less in favour of the customer is not passed for use. An electricity meter should therefore have approximately the same accuracy. As a matter of fact, it is difficult to rely upon most electric meters to register correctly, though the error is usually less than 2% at quarter-load, nor more than 3% at full load. Out of nearly 700 current motor meters of various makes tested at Munich in 1902, only 319 had an error of less than 4% whilst 259 had errors varying from 4% to 10%. If possible, however, it is desirable that the maximum error of a meter should be less than 2% at quarter-load, or nor more than 3% at full load. The accuracy of a meter is tested by drawing calibration curves showing the percentage departure from absolute accuracy in its reading for constant load and for different load conditions. The meter is determined with an accurate ammeter or watt-meter the current supplied to a circuit for a period measured by a good clock and comparing this with the actual reading of the meter.

METHODOISM

during the same time. A common source of trouble is the short circuiting of the shunt coils owing to the shellaced cotton covering of the wire becoming moist.

A good meter should start with a current which is not more than 2½% of its rated value when there is a pressure of 200 volts. A 5 c.p. carbon filament lamp takes only 0·1 ampere; hence unless a meter will begin to register at 0·1 ampere it will fail to record the current consumed by a single small incandescent lamp. In large supply meters it falls rather than a serious revenue.

The resistance of the meter coils causes a fall in voltage down the series coil which reduces the supply pressure to the consumer. On the other hand the resistance of the shunt coil absorbs energy which generally varies from 1 to 3 watts and is a liability to the consumer or to the supply company according to the manner in which the shunt coil is connected. In those meters which are compounded—that is, have a shunt coil wound on the field magnets to compensate for the friction of the train—it is important to notice whether the consumer is directly connected with the supply, or whether the supply is made up of separate conductors. There is no current in the series coil, since a meter which "runs on the shunt" runs up a debt against the consumer for which it gives no corresponding advantage.

Generally speaking, the price of the meter is a subordinate consideration. Since the revenue-earning power of a supply station depends entirely upon its meters, inaccuracy in meter record is a serious matter.

The cost of measuring current by the aid of an ammeter is roughly (1) the cost of the three parts of the meter, which varies from £2 to £6 for an ordinary light-house electric meter; (2) the capital value of the energy absorbed in it, which if the cost of the energy is taken at 2d. per Board-of-

The Wesleyan Methodists now represent the original body as founded by John Wesley in Great Britain and Ireland; but in America those who looked upon him as their founder adopted the episcopal mode of Church government after the War of Independence, and have since that time been known as Episcopal Methodists (see below). It should be noted that the Welsh Calvinistic Methodists are only slightly connected with the original body. They were indirectly the outcome of the evangelistic efforts of Howell Harris and Rowlands. Their work received the patronage of the Duke of Wellington, who, as Duke of Cumberland, was the Countess of Huntingdon (see CALVINISTIC METHODISTS). For a time Whitefield was leader, and we find a reference to the "Whitefieldian and Wesleyan Methodists" in the Supplement to the Gentleman's Magazine for 1747, p. 619. The theological views of these teachers proved quite incompatible with the Arminianism of Wesley, and a definite breach between them and him took place in 1770. The Welsh Calvinistic Methodists are now a branch of the Presbyterian Church. Other divisions have been formed at various times by secessions from the Wesleyan Methodists (see separate articles). They are: Methodist New Connexion (founded 1797–1798); Bible Christians (1815); United Methodist Free Churches 4 (about 1836); Primitive Methodists (founded 1807–1810); Independent Methodist Churches (about 1806); Wesleyan Reform Union (1850, reorganized 1859). These bodies have separated solely on matters of Church government and not on points of doctrine. The Primitive Methodists in Ireland 5 were a small body who in 1817 seceded because they wished to maintain that close connexion with the Church of England which existed at the time of Wesley's death, but in 1878 they rejoined the parent body. Methodism has always been aggressive, and her children on emigrating have taken with them their evangelistic methods. (For the American branches see below.)

The statistics given in the following table (not including Junior Society Classes) are from the Minutes of the Conference of the Wesleyan Methodist Church for 1909. At the death of Wesley the figures were: 113 preachers, 119 circuits and mission stations, and 76,968 members. In the United States: 97 circuits, 198 preachers and 43,265 members.

In 1837 a preachers in Great Britain and Ireland was 318,716; 5
5 In America there were 66,007; in Upper Canada, 14,000; while the American Churches had charge of 650,678 members. Total for the world: 1,049,401, with 4478 ministers.

Three Oecumenical Conferences have been held—two at City Road, London, in 1881 and 1901, and one at Washington in 1891. The numbers represented at these Conferences during the preceding decade had gained about a million members and three million adherents. At the same time there has been a steadily increasing number of preachers in the United Methodist Church.

1. These first three were joined in 1907 under the name of the United Methodist Church.

of the Christian—which attracted attention, gave them distinct, and even aroused ridicule and opposition. Wesley and his helpers, finding the Anglican churches closed against them, took to preaching in the open air; and this method is still followed, more or less, in the aggressive evangelical work of all the Methodist Churches. As followers rapidly increased they were compelled to hold their own Sunday services, and this naturally led them to appoint as preachers godly laymen possessing the gift of exhortation. These followed their ordinary avocations on week-days, but on Sundays preached to congregations in their own immediate neighbourhood, and hence were called local preachers as distinguished from travelling preachers. The extent to which the employment of the local preacher is characteristic of Methodism may be seen from the fact that in the United Kingdom while there are only about 3000 Methodist ministers, there are more than 18,000 congregations; some 13,000 congregations, chiefly in the villages, are dependent on local preachers.

In the organization adopted to foster spiritual life the very characteristic "Class-meetings for Christian fellowship" take a prominent place. Membership in the church depends solely upon being enrolled as a member of one of these meetings for Christian fellowship, and thus placing oneself under pastoral oversight.

The Wesleyan Methodists now represent the original body as founded by John Wesley in Great Britain and Ireland; but in America those who looked upon him as their founder adopted the episcopal mode of Church government after the War of Independence, and have since that time been known as Episcopal Methodists (see below). It should be noted that the Welsh Calvinistic Methodists are only slightly connected with the original body. They were indirectly the outcome of the evangelistic efforts of Howell Harris and Rowlands. Their work received the patronage of the Duke of Wellington, who, as Duke of Cumberland, was the Countess of Huntingdon (see CALVINISTIC METHODISTS). For a time Whitefield was leader, and we find a reference to the "Whitefieldian and Wesleyan Methodists" in the Supplement to the Gentleman's Magazine for 1747, p. 619. The theological views of these teachers proved quite incompatible with the Arminianism of Wesley, and a definite breach between them and him took place in 1770. The Welsh Calvinistic Methodists are now a branch of the Presbyterian Church. Other divisions have been formed at various times by secessions from the Wesleyan Methodists (see separate articles). They are: Methodist New Connexion (founded 1797–1798); Bible Christians (1815); United Methodist Free Churches 4 (about 1836); Primitive Methodists (founded 1807–1810); Independent Methodist Churches (about 1806); Wesleyan Reform Union (1850, reorganized 1859). growing feeling in favour of union. Canada and Australasia led the way, for in these countries the Methodist Church was undivided, and the sentiment was greatly strengthened by the formation in the United Kingdom of the United Methodist Church in 1867. See A New History of Methodism, ed. W. J. Townsend. H. B. Workman, George Eayrs (2 vols., London, 1909). (J. A. V.)

**METHODISM**

discipline, and Wesley, hearing of the disagreement, in 1773 appointed Thomas Rankin (c. 1738-1810) superintendent of the entire work of Methodism in America.

**The First American Conference.**—The first American Conference was held in 1773, and consisted of ten preachers, all of whom were born in England or Ireland. Asbury came to America to remain permanently, but Rankin, unable to identify himself with its people, to take the test oaths required in the Revolution, or to sympathize with the colonies, returned to England, as did all the English preachers except Asbury. By May 1776 there were 24 preachers and 4921 members; but in the first year of the Revolution there was a loss of 7 preachers and nearly 1000 members. The next year saw extensive revivals, in sections removed from the seat of war, which added more than 2600 to the number of members.

The preachers in the South determined upon administration of the sacraments, and a committee was chosen whose members ordained themselves and others. The Northern preachers opposed this step and for several years the Connexion was on the verge of disruption. An agreement was finally made to suspend the administration until Wesley's desires and judgment could be ascertained. He perceived that the society would disintegrate unless effective measures were speedily taken, and, aided by two presbytery of the Church of England, early in 1784 he ordained Thomas Coke (1747-1814), already a presbyter of that Church, as superintendent. He likewise ordained two of his lay preachers as deacons and elders, to accompany Coke, whom Wesley sent to America as his commissioner to establish, for the Methodist Society, a system of Church government, which should include the administration of Baptism and of the Lord's Supper. Coke above. The 1880 returns are: Bulgaria, 546 members; Denmark, 3771; Finland and St Petersburg, 1367; France, 221; Italy, 3669; 49th Germany, 12,886; Norway, 6054; South Germany, 11,808; Sweden, 154,430; Switzerland, 9419.

**Methodism in the United States**

There are in the United States sixteen distinct Methodist denominations, all agreeing essentially in doctrine. John Wesley had been organizing his United Societies for more than twenty years before the movement took root in North America.

**A. Episcopal Methodist Churches.**

Philip Embury (1729-1775), a Wesleyan local preacher, emigrated in 1760 from Limerick to New York. Robert Strawbridge (1729-1781), a local preacher and native of Ireland, settled in Maryland. In 1766 Embury was stimulated by his relative, Mrs Barbara Heck, to begin Methodist preaching; and a society was soon formed, which grew rapidly. Embury was reinforced by the arrival of Thomas Webb (1724-1796), an English local preacher and a captain in the British army; and Thomas Taylor, a layman of superior ability, appealed to Wesley to send over missionaries, and the 26th annual British Conference, held in 1768, sent to the society in New York £50 and furnished passage money for two missionaries, Richard Boardman and Joseph Pilmoor (1739-1825). Three years later Francis Asbury was sent over, and was made assistant superintendent. Meanwhile Strawbridge had been preaching with success in Maryland and in Virginia.

These "advance agents" of this spiritual propaganda brought with them Wesley's Arminian theology. They brought also the "means of grace" on which Wesley placed the greatest stress; such as personal testimony in private and public, class and prayer meetings, watch-nights, love-feasts, the direct and fervent preaching of the Gospel and the singing of Wesleyan hymns, carried on by means of circuits and stations, exhorters, superintendents, and Wesley, hearing of the disagreement, in 1773 appointed Thomas Rankin (c. 1738-1810) superintendent of the entire work of Methodism in America.

The First American Conference.—The first American Conference was held in 1773, and consisted of ten preachers, all of whom were born in England or Ireland. Asbury came to America to remain permanently; but Rankin, unable to identify himself with its people, to take the test oaths required in the Revolution, or to sympathize with the colonies, returned to England, as did all the English preachers except Asbury. An agreement was finally made to suspend the administration until Wesley's desires and judgment could be ascertained. He perceived that the society would disintegrate unless effective measures were speedily taken, and, aided by two presbytery of the Church of England, early in 1784 he ordained Thomas Coke (1747-1814), already a presbyter of that Church, as superintendent. He likewise ordained two of his lay preachers as deacons and elders, to accompany Coke, whom Wesley sent to America as his commissioner to establish, for the Methodist Society, a system of Church government, which should include the administration of Baptism and of the Lord's Supper. Coke above. The 1860 returns are: Bulgaria, 546 members; Denmark, 3771; Finland and St Petersburg, 1367; France, 221; Italy, 3669; 49th Germany, 12,886; Norway, 6054; South Germany, 11,808; Sweden, 154,430; Switzerland, 9419.
was furnished by Wesley with a document setting forth the grounds on which he had taken this step. Wesley also appointed Thomas Coke and Francis Asbury "to be joint superintendents over our brethren in North America." Soon after Coke and his companions arrived they met Asbury and fifteen preachers, and a special conference was called, which opened on the 24th of December 1784, in the suburbs of Baltimore, Maryland. This convention organized itself into a Methodist Episcopal Church, in which the liturgy sent by Wesley should be read, and the sacraments should be administered by superintendents, elders and deacons, these elders and deacons to be ordained by a presbytery using the episcopal form. Coke and Asbury were unanimously elected superintendents, Coke, aided by his clerical companions from England, ordaining Asbury as deacon and elder and formally consecrating him a general superintendent. Several elders were ordained. This convention adopted the first Discipline of the Methodist Episcopal Church. It adopted the existing doctrinal standards, consisting chiefly of Wesley's Notes on the New Testament; also twenty-five of the Articles of Religion of the Church of England, modified so as to eradicate all trace of High Church ritualism, Anglican or Roman, and the distinctive doctrines of Calvinism.

The Church thus established began its ecclesiastical career with 18,000 members, 104 travelling preachers, about the same number of local preachers, and more than 200 licensed exhorters. There were 60 chapels and 800 regular preaching places.

The energy of Asbury, and the position of Coke in the Church of England, his wealth, culture, and preaching power, greatly reinforced the efforts of the preachers. The administration of the sacraments brought peace; and many who would not unite with the "Society" asked admission to the Church. Within five years the number of preachers swelled to 227, and the members to 45,949 (white) and 11,682 (coloured).

To bind the whole body the existing method required the concurrence of all the preachers. Every member concurred in every proposition. This was inconvenient and occasioned much loss of time; therefore a General Conference was established to meet once in four years. The first was held in 1792, and therein arose a sharp conflict. James O'Kelly (1735-1826), a Presiding Elder in control of a large district, proposed that, when the list of appointments was read in the Conference, if any preacher was not pleased with his assignment he might appeal to the Conference. The motion being lost, O'Kelly and several other preachers seceded. The Conference in 1804 limited the power of the Bishops by forbidding them to appoint any pastor for more than two consecutive years in charge of the same church. As all "travelling preachers" were eligible, without election, to seats in General Conferences, widespread dissatisfaction prevailed among the distant Conferences. The era of the steamboat and the railway not having arrived, it was possible for two Annual Conferences, and adjourned to the seat of the General Conference, to cut out all others combined. This led to a demand for the substitution of a delegated General Conference, which was conceded by the Conference of 1808 to take effect four years later. The office then known as the Presiding Eldership had become powerful: Bishops appointed the pastors to churches, Presiding Elders to districts; but it was the purpose of the majority to transfer to the Annual Conferences the power of appointing Presiding Elders. The change, though discussed for many years, has not been accomplished.

Several issues had been settled; but one, that of slavery, had to be faced. The storm burst on the Conference of 1848. Bishop James Osgood Andrew (1794-1871), a native of the South, had, by inheritance and marriage, become a slaveholder. After debates of many days, he was requested "to desist from the exercise of the office of Bishop while this impediment remained." The Southern members declared that the infraction of such a stigma upon Bishop Andrew would make it impossible for them to maintain the influence of Methodism in the South, and a tentative plan of separation was adopted by the Conference by an almost unanimous vote. The result was that the Methodist Episcopal Church was bisected, and when the General Conference of 1848 convened it represented 780 travelling preachers and 532,200 members fewer than it had numbered four years before.

After the Civil War the increase in membership was noteworthy. The quadrennial Conference of 1868 represented 222,687 members more than its predecessor; of this gain 117,326 were in the Southern States. In 1872 lay representatives were admitted, the Constitution having been amended so as to make it legal. It was not, however, an equal representation, for though ministerial Conferences were represented according to their number, in no circumstances could there be more than two lay representatives from one Annual Conference. Not till 1900 were lay and clerical representation equalized. In 1864 the time limit of pastorates was lengthened to three years, and in 1888 to five years. This limit was taken off in 1900, and pastors can be reappointed at the will of the Bishop.

Five women presented credentials as lay delegates in 1888. Their eligibility was questioned; and they were denied admission. For the next four General Conferences the struggle for the admission of women recurred. In 1900-1904 a general revision of the Constitution took place, and the words "lay members" were substituted for "laymen" in that part of the Constitution which deals with the eligibility of delegates to the General Conference.

The General Conference has power to make rules and regulations for the Church, subject only to restrictions which protect the Standards of Doctrine, the General Rules, the disposition of the property of the Book Concern and its income, the income of the Chartered Fund, and the right of ministers to trial before a jury of their peers, an appeal, and similar rights of the laity. By a two-thirds vote of a General Conference, and two-thirds votes of the members of the Annual Conference, and of the members of the Lay Electoral Conferences, present and voting, what is said in these "Restrictive Rules" can be altered or repealed.

The Board of Foreign Missions carries on extensive operations in China, Japan, Korea, India and Malaysia, Italy, South America and Mexico. It assists the Methodist Churches organized in Norway, Denmark, Finland, Sweden, and Iceland, and has recently established missions in Russia and France.

The Board of Home Missions and Church Extension supplies the foreign peoples domiciled in the United States with ministers of all English-speaking churches. It assists all English-speaking churches in need of help, and secures, by gifts and time loans, the erection of churches wherever needed. Invaluable coadjutors of these Boards are the Women's Foreign Missionary and the Women's Home Missionary societies.

The Board of Education, with the aid of a University Senate, assists young people to obtain education, and raises the standard of seminaries, colleges and universities. The Church, in the United States, supports 54 colleges and universities and 10 theological seminaries. The Freedmen's Aid Society is devoted to the educational needs of the negro race in the United States, in which work it has been very successful.

The Sunday School Union, Epworth League, Methodist Brotherhood, hospitals, homes for the aged, deaconesses and children's institutions are maintained by an increasing army of workers.

The whole number of ministers (exclusive of foreign missions) in 1907, was 17,694; churches, 27,691; communicants, 2,984,261.
METHODOISM

The Methodist Episcopal Church South.—After the adjournment of the General Conference of 1844, the representatives of thirteen Conferences covering the states holding slaves appealed to their constituents to determine what should be done to prevent Methodism in the South from being deprived of its influence over the whites and of the privilege, till then fully accorded, of preaching the Gospel and teaching its precepts to slaves. In 1845 a representative Convention was called; this body, with the approval and participation of Bishop Andrew, organized the Methodist Episcopal Church South. At its first General Conference, in 1846, the senior Bishop of the Methodist Episcopal Church, Joshua Soule (1781–1867), offered himself to the Church, which accepted him in his episcopal capacity. William Capers (1790–1855) and Robert Paine (1799–1838) were elected to the Episcopacy. The Church thus formed began with 460,000 members, of which 3972 were Indians, 124,691 coloured, and 1521 travelling ministers.

A difficulty arose on the division of the property of the Book Concerns, which the Methodist Episcopal Church maintained involved a change in the Constitution. A vote to authorize the division failed, and the Methodist Episcopal Church South, hopeless of relief, brought two suits, one against the Book Concern in New York, and the other against the Book Concern in Cincinnati. The former was decided in favour of the Methodist Episcopal Church South, and the latter in favour of the Methodist Episcopal Church. In the latter case an appeal was taken by the Methodist Episcopal Church South to the Supreme Court of the United States, which body unanimously decided that the Methodist Episcopal Church South was an integral part of the Methodist Episcopal Church which owned the Book Concerns, and ordered that the Southern Church should receive a proportionate part of the property of both Book Concerns. The amount ordered by the Court was in due time received.

The membership of the Church in 1850 was more than three-quarters, but the Church was doomed to feel the force of the destructive elements of the Civil War. In April 1862 New Orleans was in possession of the Federal Government, rendering it impossible to hold the General Conference due at that time and place.

At the close of the war the Missionary Society of the Church was $50,000 in debt, the Publishing House practically in ruins, and of the more than 200,000 coloured members in 1860 there remained fewer than 50,000. The Conference of 1866 convened in New Orleans. Radical changes in polity were effected. Attendance upon class meetings, which, from the origin of the Church had been obligatory, was made voluntary, and the rule was repealed which required a probation of six months before admission into full membership. The time limit on the continuation of pastorate was extended from two to four years. The most radical change was the introduction into the General Conference of a number of lay representatives equal to the number of clerical, and the admission into each Annual Conference of four lay delegates for each Presiding Elder's district.

The coloured people, with the consent of the Church, withdrew in 1870, and formed a new Church called the Coloured Methodist Episcopal Church.

The most striking denominational effort in its history was the maintenance of the solvency of the Publishing House, which was seized by the Federal Troops, and used as a United States printing office; with the damage done, and debts incurred in rebuilding, after a fire, interest, &c., the liabilities were $35,000, with debts $125,000 in excess of assets. The concern was declared insolvent, but the necessary funds were forthcoming, and the honour of the Church was maintained.

Education has received unceasing attention. The titles to 175 institutions are held by the Church, and the list of colleges and theological seminaries is a credit to the denomination. The most important is Vanderbilt University, at Nashville, Tennessee, founded in 1872, and largely endowed by members of the family whose name it bears. The chief foreign missions are in China, Mexico, Brazil, Japan, Korea, and Cuba. Its mission in Japan and the mission of the Methodist Episcopal Church and the Methodist Church of Canada were united in 1907 in a new organization entitled the Methodist Church of Japan. A distinguishing feature of this church is a practical veto power possessed by the bishops, to be exercised when the conference adopts any measure which in their opinion is not consistent with the spirit of Methodism. They have the right to present written objections and should the General Conference, by two-thirds vote adhere to its action, the proposal is sent down to the Annual Conference for ratification; otherwise it is killed. Fraternal relations between the Episcopalian and the Methodist Churches were fully established in 1876, and have broadened in spirit and scope from that time.

The Methodist Episcopal Church South in 1870 had 6774 ministers, 16,069 churches and 1,631,379 communicants.

The African Methodist Episcopal Church.—This body originated in strained relations between the white and coloured Methodists of Philadelphia, Pennsylvania, the result of which was, that the coloured people proceeded to organize their own Church body.

They adopted as their standards the doctrines of the Methodist Episcopal Church, and, with a few modifications, its form of government. The Church steadily prospered, but for several years not proportionately in the North, while the Southern Conference, which had Payne (1811–1893), who had studied in the Gettysburg Theological Seminary, led a reform, which involved a marked elevation of the qualifications for ministers, and from that time the body has constantly grown in the South. One of its peculiarities is that the bishops are members of the General Conference. It sustains Wilberforce University (at Wilberforce, Ohio) and other educational institutions, and has missions in Africa, South America, the West Indies and Hawaii. It offers help to the present, but among its members, who have added greatly to the respect felt for their race and Church. The African Methodist Episcopal Church is the largest Christian denomination consisting wholly of the Negro race. In 1897 comprised 6900 ministers, 5321 churches, and 842,023 communicants.

The African Methodist Episcopal Zion Church.—Some of the coloured people in the city of New York, "feeling themselves appraised, after prolonged treatment as coloured people, that Church privileges permitted to others," organized among themselves, in 1796, and in the year 1800 built a church and named it Zion. For twenty years the Methodist Episcopal Church supplied this church with its ministers. In 1821, the coloured members, in white robes, requested the bishops to ordain them as elders, three of their number a bishop. As late as 1864 the Church had only 92 ministers and 5000 members, but in twelve years it doubled its membership more than five times. In this Church the sexes are equally eligible to all positions. Its educational operations at first were failures, but gradually became successful. Its foreign missions were made a separate department in 1884. This Church had, in 1897, 3871 ministers, 5200 churches and 573,107 communicants.

The Coloured Methodist Episcopal Church.—In 1866 the General Conference of the Methodist Episcopal Church South authorized the bishops to organize its coloured members into an independent ecclesiastical body, if it should appear that they desired it. The bishops formed a number of Annual Conferences, consisting wholly of coloured members, and requested the appointment of five commissioners of the Caucasian part of the Church to meet five of their own number to create an independent Church. Two Bishops of the Methodist Episcopal Church were admitted to the Episcopacy. The colored Church, organized as the Coloured Methodist Episcopal Church, was composed of two races, the Caucasian elders, selected by the eight coloured conferences. The coloured people by vote named the organization the Coloured Methodist Episcopal Church.

The Union American Methodist Episcopal Church agrees in doctrines and usages with other Methodist bodies. It is divided into Conferences and elects its Bishops for life. It had in 1907, 18,500 members, 138 ministers and 255 churches.

B.—Non-Episcopal Methodist Churches.

The Methodist Protestant Church.—In 1821 ministers and laymen of the Methodist Episcopal Church began to criticize its polity, and when their utterances became aggressive the adherents to the regular order replied with equal vigour. During the General Conference of 1824, held in Baltimore, a Convention of "Reformers" met, and established a periodical entitled the Mutual Rights of the Ministers and Members of the Methodist Episcopal Church, and made arrangements to organize Union Conferences. The first General Conference was expelled for schism and spreading incendiary publications. Prior to the Conference those expelled, and their sympathizers, formed themselves into a society named "Associate Methodist Reformers." These sent memorials to the General Conference of 1828, and issued addresses to the public. After a powerful and painful discussion, the appeals of the expelled members...
The controversy centered upon lay representation, the episcopacy and the presiding eldership.

A General Convention was held on the 2nd of November 1830, a Union was adopted, and a new organization was established, styled the Methodist Protestant Church. Within eight years it had acquired 30,000 members, the majority of whom were in the South and bordering states. The Methodist Protestant Church has a presbyterial form of government, the powers being in the Conference. There is no episcopal officer. The General Superintendent; each Annual Conference elects its own officers. Its General Conference meets once in four years. Ministers and laymen equal in number are elected by the Annual Conferences, in a ratio of one delegate for 1000 members. The General Conference of the Methodist Episcopal Church of 1908 sent delegates to the Conference of the Methodist Protestant Church, making overtures toward an organic union, but formal negotiations have not been instituted. This Church had, in 1907, 1551 ministers, 2242 churches and 183,894 communicants.

The Wesleyan Methodist Connection or Church of America.—In the Methodist Episcopal Church slavery was always a cause of contention. In 1842 certain Methodist abolitionists declared as to the Union of Seeding. Among the leaders were Orange Scott (1808–1847), Joseph Horton and Le Roy Sunderland (1822–1885) and in a paper, which they had established, known as The True Wesleyan, they announced their withdrawal from the Church, and issued a call for a convention of all like-minded, which met on the 31st of May 1843, at Utica, New York, and issued the Wesleyan Methodist Connection or Church of America. The enterprise started with 6000 laymen and 22 travelling ministers of the Methodist Episcopal Church, and nearly as many more from the Methodist Protestant Church and other small bodies of Methodist antecedents. Its General Conference has an equal number of ministers and laymen. In less than eighteen months this body had gained in members 250%, but as the Methodist Episcopal Church purged itself from slavery in 1844, and slavery itself was abolished in 1862, a large number of ministers and laymen withdrew from the Church. The decision of the Lower Church may be taken to a District Conference. In 1907 the body had, in 1907, 539 ministers, 600 churches and 15,587 communicants.

The Congregational Methodists originated in Georgia in 1852; but in politics they are not strictly Congregational in the Church, and deny the episcopal form of government. They met in convention in the United States in 1860, and denounced the presence of slavery. In the Methodist Episcopal Church, the Rev. B. T. Roberts, the ablest among them, was reprimanded by the Bishop presiding in the Annual Conference, and next year he was expelled. Similar proceedings were taken against others, who appealed to the General Conference of 1860, but their expulsion was confirmed. It was the purpose of the founders to conserve the unity and the spirit of primitive Methodism. The government of the Church is simple, all in all, the episcopacy and its adjuncts resembling that of the Church whence it sprang. The Methodist Church had, in 1907, 1032 ministers, 1106 churches, and 31,467 communicants.

Methodist Churches.—The Primitive Methodist Church, as it exists in the United States, came from England. In 1877 it reported 7013 communicants. The Independent Methodists are composed of congregations in Maryland, Tennessee and the District of Columbia. In 1906 it had over 3000 members in 1907. The Evangelical Missionary Church is composed of the dissenters from the African Methodist Episcopal Church, who in 1886 withdrew from the African Methodist Episcopal Church. They had in 1907 about 5000 members. The New Commission of the New African Methodist Episcopal Church, in 1907, withdrew from the Methodist Episcopal Church South, in Georgia, and in 1908 organized a new body, the New African Methodist Episcopal Church. The African Union Methodist Protestant Church dates from 1816, and differs from the African Methodist Episcopal Church in organization. The Disciples of Christ, a church in paid ministers, and Episcopacy. In 1907 it had 3867 members in 200 churches. The American Appalachian Church was organized in 1896, in Virginia. It was reported in 1890 to have 2346 communicants, and shows no gain at the present time.

Methodist New Connexion,—A Protestant Nonconformist Church, formed in 1797 by secession from the Wesleyan Methodists, and merged in 1907 into the United Methodist Church (q.v.). The secession was led by Alexander Kilham (q.v.), and resulted from a dispute regarding the position and rights of the laity, Kilham and his party desiring more power for the members of the Church and less for the ministers. In its conferences ministers and laymen were of equal number, the laymen being chosen by the circuits and in some cases by “guardian representatives” elected for life by conference. Otherwise the doctrines and form of the Connexion were the same as those of the Wesleyans. At the time of the union with the Bible Christians and the United Methodist Free Church in 1907 the Methodist New Connexion had some 250 ministers and 45,000 members.

Methodius (c. 825–885), the apostle of the Slavs, was a native of Thessalonica, probably by nationality a Graecized Slav. His father’s name was Leo, and his family was socially distinguished; Methodius himself had already attained high official rank in the government of Macedonia before he determined to become a monk. His younger brother Constantine (better known as Cyril, the name he adopted at Rome shortly before his death) was a friend of Photius, and had earned the surname “the Philosopher” in Constantinople before he withdrew to monastic life. Constantine about 860 had been sent by the emperor Michael III. to the Khazars, a Tatar people living north-east of the Black Sea, in response to their request for a Christian teacher, but had not remained long among them; after his return to within the limits of the empire, his brother Methodius worked among the Bulgarians of Thrace and Moesia, baptizing their king Bogors in 861. About 863, at the invitation of Rastislav, king of Great Moravia, who desired the Christianization of his subjects, but
at the same time that they should be independent of the Germans, and, the two brothers went to his capital (its site is unknown), and, besides establishing a seminary for the education of priests, successively occupied themselves in the vernacular tongues and in diffusing their translations of Scripture lessons and liturgical offices. Some conflict with the German priests, who used the Latin liturgy, led to their visiting Pope Nicholas I., who had just been engaged in his still extant correspondence with the newly converted Bulgarian king; his death (in 867) occurred before their arrival, but they were kindly received by his successor Hadrian II. Constantine died in Rome (in 869), but Methodius, after satisfying the pope of his orthodoxy and obedience, went back to his labours in “Moravia” as archbishop of Syrmia (Sirmium) in Pannonia. His province appears to have been, roughly speaking, co-extensive with the basins of the Raab, Drave and Save, and thus to have included parts of what had previously belonged to the provinces of Salzburg and Passau. In 871 complaints on this account were made at Rome, nominally on behalf of the archbishop of Salzburg, but really in the interests of the German king and his Germanizing ally Swatopulok, Rastislav’s successor; they were not, however, immediately successful. In 879, however, Methodius was again summoned to Rome, but on the 1st III., after hearing the pope and the bishops on the service of celebrating mass in the Slavonic tongue, but, owing to the peculiar delicacy of the relations of Rome with Constantinople, and with the young church of Bulgaria, the pope, contrary to all expectation, ultimately decided in favour of a Slavonic liturgy, and sent Methodius (880) back to his diocese with a suffragan bishop of Neitra, and with a letter of recommendation to Swatopulok. This suffragan, a German named Wiching, unfortunately proved the reverse of helpful to his metropolitan, and through his agency, especially after the death of John VIII. in 882, the closing years of the life of Methodius were embittered by continual ecclesiastical disputes, in the course of which he is said to have laid Swatopulok and his supporters under the ban, and the realm under interdict. The most trustworthy tradition says that Methodius died at Hardisch on the March, on the 6th of April 885. He was buried at Weldehrad (probably Stuhlwiesenburg).

The Greek Church commemorates St Cyril on February 14 and St Methodius on May 11; in the Roman Church both are commemorated on March 9th. Their canonization as saints (1831) in 1835 was, in view of the fact that Gregory VII. and several other popes condemned them as Arians. After the death of Methodius much of his work was undone; his successor Gosrad, a Slav, was expelled, with all the Slav priests, and the Latin language and liturgy supplanted the vernacular. On the 5th of July 1863 a millennial celebration of the two brother apostles was held by the people of Bohemia and Moravia.

See Schafarik’s Slawische Alltherlärmer; L. K. Götze, Geschichte der Slawenpostel Konstantinus und Methodius (Gotha, 1897); N. E. Wenzel, Cyrril und Methodius, das Lehrer der Slaven (Erlangen, 1885), and art. in Hauck-Herzog’s Realencycl. für prot. Theol. iv. 384, where the literature is cited; G. F. Maclear, Conversion of the Slavs (London, 1879).

METHUEN, BARONY OF. The English title of Baron Methuen of Corsham (Wilt.) was created in 1838 for Paul Methuen (1777–1849), who had been a Tory member of parliament for Wiltshire from 1812 to 1819, and then sat as a Whig for North Wiltshire from 1833 to 1838. His father, Paul Methuen, was the cousin and heir of the wealthy Sir Paul Methuen (1672–1757), a well-known politician, courtier, diplomatist and patron of art and literature, who was the son of John Methuen (c. 1650–1706), Lord Chancellor of Ireland (1697–1703) and ambassador to Portugal. It was the last-named who in 1703 negotiated the famous “Methuen Treaty,” which, in return for the admission of English woollens into Portugal, granted differential duties favouring the importation of Portuguese wines into England to the disadvantage of French, and thus displaced the drinking of Burgundy by that of port. He and his son were both buried in Westminster Abbey. The 1st baron was succeeded in the title by his son Frederick Henry Paul Methuen (1818–1891), and the latter by his son Paul, 3rd baron (b. 1845), a distinguished soldier, who became a major-general in 1890, and general officer commanding-in-chief in South Africa in 1907. The 3rd baron joined the Scots Guards in 1864, served in the Ashanti War of 1874 and the Egyptian War of 1882, and commanded Methuen’s Horse in Bechuana-land in 1884–85, and the first division of the 1st Army Corps in the South African War of 1899–1902. (See TRANSVAAL.)

METHUSELAH, in the Old Testament, the seventh in descent from Adam, and father of Lamech. According to Genesis v. 21 he lived 969 years (see Bible: Old Testament, § 5. “Chronology”). The name itself has been much discussed. Holzinger interprets it as “man of the javelin”; Holmberg prefers “man of Selah,” Selah being the Hebraized form of the Babylonian Sarratu (i.e. the god Sin), and identifies it with the Φθυπιανος of Berossus. The form Methushael, used by the author of Gen. iv. 18 and by some commentators preferred for Gen. v. 21, is variously explained as meaning “man of El” (Ball), or as a transcription (Sayce) of the Babylonian Mutu-ṣa-li (possibly, “man of the goddess”).

METHVEN, a village and parish of Perthshire, Scotland, 7 V. W. by N. of Perth by the Caledonian Railway. Pop. of parish (1901), 1699. Only an aisle remains of the collegiate church founded in 1435 by the earl of Moray (d. 1437). One of the oldest villages, Methven Castle, dating partly from 1690, occupies a fine situation in a park in which stands the Pepperell oak, 18 ft. in circumference. At Dronach Haugh near the banks of the Almond, which bounds the parish on the N., the earl of Pembroke defeated Robert Bruce in 1306. At Lynedoch, his estate on the Almond, Thomas Graham (1748–1843), the Peninsular general, afterwards Lord Lynedoch, carried on many experiments in farming and stock-breeding. He formerly owned Balgowan House, about 3 m. south-west of Methven, where many years after his death the proprietor discovered, during certain alterations, the portrait of Lord Lynedoch’s wife, the Hon. Mrs Graham (a daughter of the 9th Lord Cathcart), one of Gainsborough’s masterpieces, now in the National Gallery in Edinburgh; 43 m. north-west of Methven, occupying a beautiful position in Glenamond, is Trinity College, a public school on the English model, the first of its kind in Scotland, founded in 1841 through the efforts of W. E. Gladstone, J. R. Hope-Scott, Dean Ramsay and others, and opened in the first half of the 19th century. In the same year it was founded, Methven, Sir Robert Peel, created a baronetage, and a year later (1842) Methven was made a barony. The first baronet was the 1st baronet, Sir John Methven (1819–1889), about 3 m. south-east of Methven, Montrose won the first of a series of battles over the Covenanters on the 1st of September 1644.

METHYL ALCOHOL (CH₃OH), the simplest aliphatic alcohol; an impure form is known in commerce as wood-spirit, being produced in the destructive distillation of wood. The name methyl, from Gr. μεθύo, wine, ὀδη, wood, explains its origin. Discovered by Boyle in 1661, it was first carefully studied by Dumas and Peligot in 1831; its synthesis from its elements (through methane and methyl chloride) was effected by Berthelot in 1858. It is manufactured by distilling wood in iron retorts at about 500°C., when an aqueous distillate, containing methyl alcohol, acetone, acetic acid and methyl acetic ester, is obtained. This is neutralized with lime and redistilled in order to remove the acetic acid. The distillate is treated with anhydrous calcium chloride, the crystalline compound formed with the alcohol being separated and decomposed by redistilling with water. The aqueous product is then dehydrated with potash or lime. To obtain it perfectly pure the crude alcohol is combined with oxalic, benzoic or acetic acid, and the resulting ester separated, purified, and finally decomposed with potash. Methyl alcohol is also obtained in the dry distillation of molasses. The amount of methyl alcohol present in wood spirit is determined by converting it into methyl iodide by acting with phosphorus iodide; and the acetone by converting it into iodofrom by boiling with an alkaline solution of iodine in potassium iodide; ethyl alcohol is detected by giving acetylene on heating with concentrated sulphuric acid, methyl alcohol, under the same circumstances, giving methyl ether.

Pure methyl alcohol is a colourless mobile liquid, boiling at
METICULOUS—METROCLES 299

66°-67°, and having a specific gravity of 0.8142 at 0° C. It has a burning taste, and generally a spirituous odour, but when absolutely pure it is said to be odourless. It mixes in all proportions with water, alcohol and ether. Its compound with calcium chloride has the formula CaCl₂CH₃OH, and with barium oxide BaO₂CH₂OH. Oxidation gives formaldehyde, formic acid and carbonic acid; chlorine and bromine react, but less readily than with ethyl alcohol. The chief industrial applications for making denatured alcohol (q.v.), and as a solvent, e.g. in varnish manufacture; it is also used for a fuel; a purer product is extensively used in the colour and fine chemical industries.

Methyl chloride CH₃Cl is a gas, boiling at -23°, obtained by chlorinating methane. The letter, from methyl alcohol; wood spirit is treated with salt and water, and hydrochloric acid conducted into the boiling spirit in the presence of zinc chloride, the evolved gas being washed with potash and dried by sulphuric acid. It is also prepared by heating trimethylhydrochloride. Alcohol dissolves 33 volumes and water 4. Methyl bromide is a liquid, specific gravity 1.73, boiling point 13°; methyl iodide has a specific gravity of 2.19, and boils at 43°.

METICULOUS (through Fr. méticuleux, from Lat. meticulus, timid, cautious; metic, fear), a term meaning pedantically or excessively careful of details, over-scrupulous, laying too much stress on minutiae.

METOCHTA, THEODORE [Theodoros Metochites], a Byzantine author, man of learning and statesman, who flourished during the reign of Andronicus II. Palaeologus (1282-1328). After the death of his patron, the emperor John III. Palaeologus, who was deprived of his office of great logothete (chancellor) and sent into exile. He was soon recalled, but retired from political life to a convent, where he died in 1332. He was a man of very great learning, only surpassed by Photius and Michael Psellus. His pupil Nicophorus Gregoras, who delivered his funeral oration, calls him a "living library."

Only a few of his numerous works have been preserved. The best known is Τομηματισμὸς καὶ σημειώματα γραμματ. Miscellanea philosophica historic (ed. C. G. Müller and T. Kiesling, 1821), containing some 120 essays; for a list of them see Fabricius, Bibliographia graeca (ed. Harles), x. 417; in these he chiefly made use of Synesius. Of his rhetorical pieces two have been published by C. N. Sathas in Μετοχισμάτων, βιβλίον (1872), and two poems on religious subjects by M. Treu (1895). The poems, dealing mainly with contemporary and personal matters, are written in hexameter, not in the usual "poetical" verse. Metochita was also the author of works on philosophical and astronomical subjects.

METONIC CYCLE, in chronology, a period of 19 years during which there are 235 lunations, so-called because discovered by Meton. Computation from modern data shows that 235 lunations are 6939 days, 16.5 hours; and 19 solar years, 6939 days, 14.5 hours. The relation between integral numbers of months and years expressed by Meton's rule therefore deviates only two hours from the truth. Since 19 Julian years make 6939 days, 18 hours, the relation errs by only 1.65 hours when the Julian year is taken. Meton was an Athenian astronomer (fl. 432 B.C.).

METONYMY (Gr. μετονυμία, change of name, from μετά denoting change, and νομα, name, a figure of speech, in which the name of one thing is changed for that of another, to which it is related by association of ideas, as having close relationship to one another. Thus "sceptre," "throne," "crown," are used for royal power or authority, "hearth and home" is used for "country," &c.

Synecdoche (Gr. συνεκδοχή, from συνεκδοχέας, to join in receiving) is a rhetorical figure similar to metonymy, in which the part is used for the whole or vice versa, thus "hands" is used for the members of the crew of a vessel; a regiment of infantry is said to number so many "bayonets," &c.

METOEPE (Gr. μετοπή, a middle space), a term in architecture for the square recess between the triglyphs in a Doric frieze, which is sometimes filled with sculpture.

METRE (μέτρον, sc. τέχνη, from Gr. μέτρον, measure), in prosody, the harmonious and regulated disposition of syllables into verse. Metrical form is distinguished from prose by the uniformity of corresponding lines in relation to the number of syllables and the similarity of final sound (rhyme or assonance), by the repetition of certain letters at regular intervals (in alliterative measure), or merely by the regular succession of ups and downs of intonation. In ancient classic poetry the measure which creates the metrical form consists only of this last quantitative element, which is rhythm.

For the rules and divisions of the various metrical systems, see VERSE. For the restricted use of "metre" as a unit of measurement, see METRIC SYSTEM below.

METRIC SYSTEM (adapted from Gr. μέτρος, measure), that system of weights and measures of which the metre is the fundamental unit. The theory of the system is that the metre is a part of a quadrant of the earth through Paris; the litre or unit of volume is a cube of 1 cm. metre side; the gramme or unit of weight is (nominally) a part of the weight of a litre of water at 4° C. The idea of adopting scientific measurements had been suggested as early as the 17th century, particularly by the astronomer Jean Picard (1620-1682), who proposed to take as a unit the length of a pendulum beating one second at sea-level, at a latitude of 45°. These suggestions took practical shape by a decree of the National Assembly in 1790 appointing a committee to consider the suitability of adopting either the length of the seconds pendulum, a fraction of the length of the equator, or a fraction of the quadrant of the terrestrial meridian. The committee decided in favour of the latter and a commission was appointed to measure the arc of the meridian between Dunkirk and Mont Jany, near Barcelona. Another commission was also appointed to draw up a system of weights and measures based on the length of the metre and to fix the nomenclature, which on the report of the commission was established in 1795. It was not until 1799 that the report on the length of the metre was made. This was followed by the law of December 1799 fixing definitely the value of the metre and of the kilogramme, or weight of a litre of water, and the national system became compulsory in 1807.

METROCLONIUM and METRIC SYSTEM, the latter system was legalized in some countries to be used in trade of the metric system, and abolished the penalty for using or having in one's possession a weight or measure of the common.

See also DECIMAL COINAGE AND WEIGHTS AND MEASURES.

METRICALS, a Greek philosphor of the Cynic school, was a contemporary of Crates, under whose persuasion he deserted the views of Theophrastus. It was his sister, Hipparchia, whose romantic attachment to Crates is a fascinating sidelight on the almost truculent asceticism of the Cynics. He was a man of peculiar strength of character, and esteemed the joys of life so low that he was deterred from an early suicide only by the influence of Crates. His philosophical views, which were identical with those of Crates (q.v.), he expounded by precept and example with great success, and had among his pupils
Menippus of Sinoe. Having weighed the probable pains and pleasures of approaching old age, he decided that life had nothing left for which he greatly cared, and drowned himself. He is said to have written several works, which he afterwards burnt. Of one, entitled Προσφορά, Diogenes preserves a single line (vi. 6).

METEORODORUS, the name of five philosophers.

1. Meteorodorus of Athens was a philosopher and painter who flourished in the 2nd century B.C. It chanced that Paulinus Aemilius, visiting Athens on his return from his victory over Perseus in 168 B.C., asked for a tutor for his children and a painter to glorify his triumph. The inhabitants suggested Meteorodorus as capable of discharging both duties, and it is recorded that Aemilius was entirely satisfied (see Pliny, Nat. Hist. xxv. 135).

2. Meteorodorus of Chios was an important member of the Atomic school. A pupil of Nestus, or, as some accounts prefer, of Democritus himself, he was a complete sceptic. He accepted the Democritean theory of atoms and void and the plurality of worlds, but held a theory of his own that the stars are formed from day to day by the moisture in the air under the heat of the sun. His radical scepticism is seen in the first sentence of his Περὶ φύσεως, quoted by Cicero in the Academica ii. 23 § 73. He says, "We know nothing, no, not even whether we know or not!" and maintains that everything is to each person only what it appears to him to be. Meteorodorus is especially interesting as the teacher of Anaxarchus, the friend of Pyrrho, and therefore, as the connecting link between the proper and the later scepticism. It cannot be decided whether a work entitled the Τραχύκαρος quoted by Athenaeus (iv. 184 a) is by this, or another, Meteorodorus. The same difficulty is found in the case of the Περὶ ἱστορίας referred to by the scholiast on Apollonius.

3. Meteorodorus of Lampascus was the disciple and intimate friend of Epicurus, and is described by Cicero (de Fin. ii. 28. 92) as "almost a second Epicurus." He died in 277 B.C. at the age of fifty-three, seven years before his master, who adopted his children and in his will commended them to the care of his pupils. The wife of Meteorodorus was Leontion, herself, like many other women of the time, a member of the Epicurean society. Athenaeus (vii. 270 F.) quotes from the words of Meteorodorus showing that he was in entire agreement with Epicurus, and was, if possible, even more dogmatic in his doctrine of pleasure. He censures his brother, Timocrates, who, though professing Epicurean, maintained the existence of pleasures other than those of the body.

4. Another Meteorodorus of Lampascus was a pupil of Anaxagoras, and one of the earliest to attempt to interpret Homer rationally. He explained not only the gods but also the heroes Agamemnon, Achilles, Hector, as representing primary elements and natural phenomena.

5. Meteorodorus of Stratonice was a pupil, first of Aparolodorus, and later of Carneades. He flourished about 110 B.C., and is reputed to have been an orator of great power. His defection from the Epicurean school is almost unique. It is explained by Cicero as being due to his theory that the scepticism of Carneades was merely a means of attacking the Stoics on their own ground. Meteorodorus held that Carneades was in reality a loyal follower of Plato.

METRONOME (Gr. μέτρον, measure, and νόμος, law), an instrument for denoting the speed at which a musical composition is to be performed. Its invention is generally, but falsely, ascribed to Johann Nepomuk Maelzel, a native of Ratisbon (1772–1838). It consists of a pendulum swung on a pivot; below the pivot is a fixed weight, and above it is a sliding weight that regulates the velocity of the oscillations by the greater or less distance from the pivot to which it is adjusted. The silent metronome is impelled by the touch, and ceased to beat when this impulse dies; it has a scale of numbers marked on the pendulum, and the upper part of the sliding weight is placed under that number which is to indicate the quickness of a stated note, as M.M. (Maelzel's Metronome) c=60, or c=72, or c=108, etc.

The number 60 implies a second of time for each single oscillation of the pendulum—numbers lower than this denoting slower, and higher numbers quicker beats. The scale at first extended from 50 to 100, but now ranges from 40 to 208. A more delicate ribbed pendulum, by inch, by clock-work, makes a ticking sound at each beat, and continues its action till the works run down; a still more intricate machine has also a bell which is struck at the first of any number of beats willed by the person who regulates it, and so signifies the accent as well as the time.

The earliest instrument of the kind, a weighted pendulum of variable length, is described in a paper by Étienne Loulié (Paris, 1696; Amsterdam, 1698). Attempts were also made by Enbray (1732) and Gabory (1771). Harrison, who gained the prize awarded by the English government for his chronometer, published a descriptive account of an instrument made by him in 1784. Pelletier, Abel Burja (1790) and Weiske (also 1790) described their various experiments for measuring musical time. In 1813 Gottfried Weber, the composer, theorist and essayist, proposed a weighted pendulum, and invented his Maelzel's instrument. The inventor contrived a variety of weights, and, by the use of all existing instruments, on the principle of the double pendulum, rocking on both sides of a centre and balanced by a fixed and a variable weight. He spent three years in completing it, and it is described and commented on in the Report of the Netherlands Academy of Sciences (Aug. 14, 1815). Maelzel then went to Amsterdam, saw Winkel and inspected his invention, and, recognizing its great superiority to what he called his own, offered to buy all right and title to it. Winkel refused, and so Maelzel constructed a copy of the invention which he sold to him, but to which he added nothing he did not already possess. Winkel then took this copy to Paris, obtained a patent for it, and in 1816 established there, in his own name, a manufactory for metronomes. When the impostor revisited Amsterdam, the inventor instituted proceedings against him and the Academy of Sciences, which decided in Winkel's favor, declaring that the graduated scale was the only point in which the instrument of Maelzel differed from his. Maelzel's scale was needlessly and arbitrarily complicated, proceeding from 40 to 120, by one-unit steps, whereas the scale of Winkel went from 72 to 120, by sixes from 120 to 144 and by eights from 144 to 208. Dr. Crotch constructed a time measurer, and Henry Smart (the violinist, father of the composer of the same name) made another in 1821, both before that received as Maelzel's was known in London. A new and ingenious amplification of the Maelzel clock-work, reducing to mechanical demonstration what formerly rested wholly on the feeling of the performer, under "Maelzel's metronome" has universal acceptance, the silent metronome and still more Weber's graduated ribbon are greatly to be preferred, for the clock-work of the other is liable to be out of order, and needs a nicety of regulation which is almost impossible; for instance, when Sir George Smart had to mark the traditional times of the several pieces in the Dettingen Te Deum, he tested them by twelve metronomes, no two of which beat together. The value of the machine is exaggerated, for no living performer can execute a piece in its required time throughout, and no student who could practise under the tyranny of its beat; and conductors of music, nay, composers themselves, will conduct the same piece slightly slower or quicker on different occasions, according to the circumstances of performance.

METROPOLIS (Gr. μητρόπλω, mother, τόπος, place), properly a mother-city, and so the name of the parent state from which colonies were founded in ancient Greece (see GREECE, sect. History, Ancient). The word was used in post-classical Latin for the chief city of a province, the seat of the government, and in particular ecclesiastically for the seat or see of a metropolitan bishop (see METROPOLITAN). It is thus used now for the capital of a country, which contains the various administrative buildings of the administrative departments, etc., of the State of Parliament, etc. In the United States of America, the term "metropolitan" is sometimes applied to the whole area including the "City of London," etc.; e.g. "Metropolitan Asylums Board"; and sometimes, as in "Metropolitan Police," excludes the City, which has its own police force (see London).

METROPOLITAN (Lat. metropolitanus, Gr. μητροπολίτης), in the Christian church, the title of a bishop who has the oversight over bishops of subordinate sees. In the Western church
the metropolitan is practically the same as the archbishop (q.v.); in the Eastern church he ranks above the archbishop, but below the patriarch (q.v.). Metropolitan first appear in the East in the 4th century as presiding over a province (provincia or eparchia), and they are the successors of the archbishops (archiepiscopi) of the province, which remains the normal custom both in East and West. In Africa, however, the metropolitan jurisdiction was exercised by the senior bishop (primas, primae sedis episcopus, senex) for the time being, a custom which prevailed for a time also in Spain. Thus, too, in the Scottish Episcopal Church and the Protestant Episcopal Church of America there are no metropolitans, the primas being the senior bishop.

METTSU, GABRIEL (1630–1667), Dutch painter, was the son of Jacob Metsu, who lived most of his days at Leiden, where he was three times married. The last of these marriages was celebrated in 1625, and Jacoba Garnijers, herself the widow of a painter, gave birth to Gabriel in 1630. According to Houbraken Metsu was taught by Gerard Dow, though his early works do not lend colour to this assertion. It is certain, however, that he was influenced in turn by Jan Steen, Rembrandt, and Hals. Metsu was registered among the first members of the painters’ corporation at Leiden; and the books of the guild also tell us that he remained a member in 1649. In 1650 he ceased to subscribe, and works bearing his name and the date of 1653 give countenance to the belief that he had then settled at Amsterdam, where he probably continued his studies under Rembrandt. One of his earliest pictures is the "Lazarus" at the Strasbourg Museum, painted under the influence of Jan Steen. Under the influence of Rembrandt he produced the "Woman taken in Adultery," a large picture with the date of 1653 in the Louvre. To the same period belong the "Departure of Hagar," formerly in the Thoré collection, and the "Widow’s Mite" at the Schwerin Gallery. But he probably observed that sacred art was ill suited to his temper, or he found the field too strongly occupied, and turned to other subjects for which he was better fitted. That at one time he was deeply impressed by the vivacity and bold technique of Frans Hals can be gathered from Lord Lonsdale’s picture of "Women at a Fishmonger’s Shop." What Metsu undertook and carried out from the first with surprising success was the low life of the market and tavern, contrasted, with wonderful versatility, by incidents of high life and the drawing-room. In no single instance do the artistic lessons of Rembrandt appear to have been lost upon him. The same principles of light and shade which had marked his schoolwork in the "Woman taken in Adultery" were applied to subjects of quite a different kind. A group in a drawing-room, a series of groups in the marketplace, or a single figure in the gloom of a tavern or parlour, was treated with the utmost felicity by fit concentration and gradation of light, a warm flush of tone pervading every part, and, with that, the study of texture in stuffs was carried as far as it had been by Ter Borch or Dow, if not with the finish or the "brio" of De Hooch.

Metsu went to Amsterdam before 1635, married in 1658, and became a citizen of that city in 1659. One of the best pictures of Metsu’s manhood is the "Market-place of Amsterdam," at the Louvre, respecting which it is difficult to distribute praise in fair proportions, so excellent are the various parts, the characteristic movement and action of the dramatic personae, the selection of faces, the expression and the gesture, and the texture of the things depicted. Equally fine, though earlier, are the "Sportsman" (dated 1661) and the "Tavern" (also 1661) at the Hague and Dresden Museums, and the "Game-Dealer’s Shop," also at Dresden, with the painter’s signature and 1662. Among the five examples of the painter at the Wallace Collection, including "The Tabby Cat," "The Sleeping Sportsman," which cost Lord Hertford £3,000, is an admirable example technically considered. Among his finest representations of home life are the "Repast" at the Hermitage in St Petersburg, the "Mother nursing her Sick Child" of the Steengracht Gallery at the Hague, the "Amateur Musicians" at the Hague Gallery; the "Duet" and the "Music Lesson" at the National Gallery, and many more examples at nearly all the leading European galleries.

METTERNICH-WINNEBURG, CLEMENS WENZEL LOTHAR, PRINCE (1773–1859), Austrian statesman and diplomatist, was born at Coblenz on the 15th of May 1773. His father, Count Franz Georg Karl von Metternich-Winneburg zu Beilstein, died in 1787. The elder Metternich, who had passed from the service of the archbishop-elector of Trier to that of the court of Vienna; his mother was Countess Maria Beatrix Aloisia von Kageneck. At the time of Clemens Metternich’s birth, and for some time subsequently, his father was Austrian ambassador to the courts of the three Rhenish electors, and the boy was thus from the first brought up under the influence of the tone and ideas which flourished in the small German courts that lay within the sphere of influence of the France of the ancien régime. In 1788 he went to the university of Strassburg, where he studied German constitutional law; but the outbreak of the French Revolution caused him to leave after two years. Metternich was a witness of the excesses of the mob in Strassburg, and he ascribed his life-long hatred of political innovation to these early experiences of the victory of liberal ideas. In 1790, by way of striking contrast, he was deputed by the Catholic bench of the Westphalian college of counts to act as their master of the ceremonies at the coronation of the Emperor Leopold II. at Frankfort, a function which he again performed at the coronation of Francis II. in 1792. The intervening time he spent at Mainz, attending the university and frequenting the court of the archbishop-elector, where his impressions of the Revolution were strengthened by his intercourse with the French émigrés who had made it their centre. The outbreak of the revolutionary war drove him from Mainz, and he went to Brussels where he found employment in the chancery of his father, at that time Austrian minister to the government of the Netherlands. Here, in August 1794, he issued his first publication, a pamphlet in which he denounced the "shallow pates" of the old diplomacy and argued that the only way to combat the French revolutionary armies was by a fille en masse of the populations on the frontier of France—singular views for the statesman who was destined to be the last great representative of the old diplomacy and the greater part of whose life was to be spent in combating the national enthusiasms by which the revolutionary power of France was ultimately overthrown.

After a long stay in England, where he made the acquaintance of the prince of Wales (afterwards George IV.), Metternich went to Vienna; and on the 27th of September 1795 he married at Austerlitz the Countess Eleonore von Kaufns, a grand-daughter of that Austrian chancellor who in many respects was his prototype. This alliance not only brought him great estates in Austria, but introduced him into the most exalted circles of Viennese society. Here he was well qualified to hold his own by reason of his handsome person, the exquisite courtesy of his manner, and the certain reputation for gallantry. He was not fair, however, from being a mere carpet diplomatist, his interests were many and varied, and he found time for the serious study of natural science and medicine. In December 1797 he was chosen by the Westphalian counts as their representative at the congress of Rastadt, where he remained till 1799. This was his first experience of the great world of practical politics and especially of those rough diplomatists of the Revolution of whom in his letters he has left so vivid a description. In January 1801 he was appointed Austrian envoy to the elector of Saxony. His two years’ stay at the court of Dresden was mainly useful to him by bringing him into touch with the many Russian and Polish families of importance; his serious diplomatic career did not begin till his appointment, in November 1803, as ambassador at Berlin. His instructions at the outset were to

1 The family of Metternich, originally established in the county of Jülich, can trace its descent to the middle of the 14th century. In 1637 they received from the archbishop of Trier the countships of Winneburg and Beilstein. These were confiscated in 1803, and the lands of the suppressed abbey of Ochsenhausen, with the title of prince of the Empire, were granted by the edict as compensation. The new principality was "mediatized" in 1806 in favour of Württemberg; but in virtue of their short tenure of it the descendants of Prince Metternich enjoy the privileges of mediatised princes.
prevent Prussia from joining the alliance of Russia and Great Britain against the French Republic and to make himself acceptable to the representative of France; but shortly afterwards his part was exactly reversed, owing to the shifting of political forces which led to the war of the third coalition, and he laboured to secure the adhesion of Prussia to the alliance of Austria, Russia and Great Britain against Napoleon. His diplomacy was not successful; for though Prussia ultimately signed the treaty of the 5th of November 1805 with Austria and Russia, the influence of the emperor Alexander and the wound given to his pride by Napoleon’s contemptuous violation of her territory had more to do with Prussia’s decision than Metternich’s veiled threats. His reward was the grand cross of the order of St Stephen and the appointment of ambassador at St Petersburg; but his commission to make himself acceptable to the French ambassador at Berlin was carried out to such excellent effect that, as a result of M. Lafaure’s reports, Napoleon requested that he might be appointed to represent Austria at the Tulleries, and in August 1806 Metternich took up his residence as ambassador in Paris.

This was the beginning of his ever growing influence in European affairs. Established in the diplomatic character of an ‘honourable spy’ in the very centre of Napoleon’s power, he used his influence in one of his violent tirades against personal graces at the Tulleries, but to establish relations with those elements in the society of the empire which were already intriguing against Napoleon’s power. His intimacy with Talleyrand and with Caroline Murat, Napoleon’s sister, was destined to produce notable results later. Though on the look-out, however, for any chance of weakening the French emperor’s power, Metternich was not at first sanguine of success, for he believed Napoleon to be invincible. For Austria the best policy seemed to him to be to temporize; he was willing, therefore, to co-operate with France in the agreement made between Napoleon and Alexander I. of Russia at Tilsit for the partition of the Ottoman Empire; failing the success of the efforts of Austrian diplomacy to break the Franco-Russian alliance, this would at least secure for the Habsburg monarchy a share of the spoils. With the postponement of Napoleon’s Oriental schemes, however, the situation was once more changed. During the summer of 1808 Metternich had reason to suspect fresh designs of the French emperor against Austria, and his suspicions appeared to be confirmed when, during an interview on the 13th of August, Napoleon accused the Austrian archduchess Louise, daughter of the Empress Josephine and brother of the Emperor George of Russia, of intrigues with the Count Stadion’s action in strengthening the Austrian armaments. In November Metternich was at Vienna, urging the Austrian government to an early declaration of war—for which the moment seemed to him opportune owing to the French losses in Spain, of which he had received exaggerated reports. On the 1st of January 1809 he was back in Paris, but no longer as a persona grata. At the outbreak of the war he was placed under arrest, in retaliation for the action of the Austrian government in interning two members of the French embassy in Hungary; and in June, on Napoleon’s capture of Vienna, he was conducted there under military guard. In July he was exchanged at Komárom for the French diplomatists, and he was present with the emperor Francis at the battle of Wagram. At a council held on the 7th of July it was decided, on Metternich’s initiative, to open negotiations for peace; next day Stadion tendered his resignation, which was provisionally accepted. Stadion was sent as diplomatic adviser to the headquarters of the archduke Charles, while Metternich took his place at the emperor’s side. On the 4th of August Metternich was appointed minister plenipotentiary of Austria, and soon afterwards was sent with Count Nugent to the peace conference at Altenburg, where Chamagny attended as Napoleon’s representative. The conference, however, dragged on without result, and the emperor Francis decided to open negotiations with Napoleon direct. Count Bubna was accordingly sent to Schönbrunn; the result was the French ultimatum which issued in the treaty of Schönbrunn (Vienna), signed by Prince Liechtenstein on behalf of the emperor Francis on the 14th of October 1809. With the negotiation and signature of this humiliating instrument Metternich therefore had nothing to do, though on the 8th of October he had been definitely appointed minister for foreign affairs, an office he was destined to hold for nearly forty years.

The position of the new minister was no easy one. By the treaty of Schönbrunn Austria was reduced to the position of a second-rate power, and by secret articles undertook during the continuance of the maritime war to limit her force of all arms to 150,000 men, and to dismiss from her service all officers or civil officers born in the territories of ancient France, Piedmont or the former Venetian republic. Weak as she had become, the menace of the future seemed even more disquieting. To the south she was divided from the French dominions by the Save; to the west and north the vassal states of France, traditionally her enemies, lay along the frontier; to the east was Russia, which as the reward for her alliance with Napoleon had received a portion of East Galicia as her share of the spoils, and to all appearance was firmly established in the Danubian principalities. Austria seemed hopelessly cut off from Napoleon from any chance of re-asserting her traditional preponderance in Germany, by Russia from any prospect of obtaining compensation at the expense of the Ottoman Empire. One false move on the part of those who guided its destinies, and the Habsburg monarchy must have been doomed on extinction.

The saving factor in the situation was the improbability of the alliance between Napoleon and Alexander continuing, and the immediate task of Metternich was to hasten its dissolution, while securing Austria’s safety in the East by bringing about the end of the Russo-Turkish War. It was a task of extreme delicacy; for any revelation of its true tendency might have thrown the emperor Alexander into the arms of France and plunged Austria into an unequal struggle for life and death with Russia on the banks of the Danube. Metternich was helped by the rapid development of the causes of disagreement between the French and Russian emperors. Early in 1810 Europe was full of contradictory rumours of war between France and Russia, of a marriage of Napoleon with a Russian grand duchess. Then suddenly came Napoleon’s formal request for the hand of the Austrian archduchess Marie Louise. A proposal so nicely calculated to forward Metternich’s plans was suspected of being due to his inspiration; certainly it was his influence that decided the emperor Francis to agree to an alliance which could not but be distasteful to him and was resented as a crowning humiliation by him and his family.

On the 13th of March 1810 Metternich left Vienna for Paris in company with the archduchess. His object was to use so favourable an occasion for obtaining the abrogation of some of the more onerous articles of the treaty of Schönbrunn, and for coming to some arrangement whereby the serious inconvenience caused in Austria by Napoleon’s coercion of the pope might be obviated. His diplomacy, however, met with but slight success. His efforts to persuade Pius VII. to purchase a measure of liberty of action by concessions to Napoleon broke down on the gentle old man’s refusal to traffic with his principles. From Napoleon he extracted a lame apology for the execution of Andreas Hofer, the reversal of a few sequestrations and, as a crowning grace, the abrogation of the article of the Schönbrunn treaty limiting Austrian armaments. In the matter of restoring the access of Austria to the Adriatic, Napoleon would make no concession; his answer to Metternich’s representations was only a commercial treaty which failed to obtain ratification at Vienna. Anything further, e.g. an exchange of the Illyrian provinces for Galicia, must depend on the attitude of Austria in the forthcoming Russian war which, in an interview of the 20th of September, Napoleon declared to be now inevitable.

On the 10th of October Metternich was back in Vienna, where his presence was urgently needed. The policy of a Franco-Austrian entente was popular with the public and the army, resentful of the treacherous attitude of Russia in the late war, but in the powerful circles of the court it had scarce an adherent. Prince Metternich himself, who had acted as foreign secretary during his son’s absence, favoured an understanding with Russia,
and was even believed to be intriguing to retain the portfolio of foreign affairs, which would have meant the victory of the Russian party. On the other hand, the French party were clamouring for the speedy conclusion of a definite alliance with Napoleon. By an admirably clear exposition of the situation Metternich won over the emperor Francis to that middle course, the policy of armed abstention, which was to be the basic principle of his diplomatic action during the crisis of the coming years. An alliance with Russia, he argued, would be worse than useless; Austria would at any time obtain better terms from the tsar’s growing needs. An alliance with France would be one with “a power whose exclusive object is the destruction of the old order of things, which has hitherto found its defence in Austria.” Alone of European Powers Austria still had the possibility of choice; let her work for the preservation of peace and at the same time remain free, should war break out, to make her own terms. It would little serve Austria’s interests to become the ally of Russia, merely to serve as a barrier behind which the emperor Alexander could carry out his designs on Turkey in safety. In an interview with Count Shuvalov, the Russian agent, Metternich roundly declared that the maintenance of the integrity of Turkey was for Austria the question in which she had to take the lead.

With the approach of the Russo-French War the situation became increasingly difficult. The partisans of a Russian alliance remained powerful and clamorous; but Metternich did not share the doubts as to the outcome of Napoleon’s invasion of Russia, which he believed would leave Austria, if she remained neutral, isolated amid a huge European confederation. To him the only safe course seemed to be to offer the French emperor substantial assistance, stipulating for some quid pro quo in the settlement to follow the war. The emperor Francis shared this view; and on the 14th of March a treaty of alliance was signed by which Austria agreed to support the French army with an army corps of 30,000 men operating from Galicia. This treaty was ratified at Vienna on the 25th of March, the day of Napoleon’s passage of the Niemen. It was characteristic of Metternich’s diplomacy that the Austrian generals in Galicia were ordered to act only on the defensive, and that the court of St. Petersburg was informed that Austria would only take part in the war as a principal should Russia force her to do so.

This cautious attitude was soon justified by the astounding developments of the Moscow campaign. When the full extent of the catastrophe that had overwhelmed Napoleon’s army became known, Metternich realized the advantageous position in which Austria lay for exploiting the changed situation. His first idea was that France should commission Austria to mediate a peace in Russia and in England (Despatch of Otto, November 10); but, as affairs developed, this was replaced by the policy of temporizing until Austria should be in a position to intervene with decisive effect. Napoleon’s demand that Austria should raise her contingent from 30,000 to 100,000 men was, indeed, from Metternich’s point of view doubly opportune: for it enabled him quietly to assume that the treaty of the 14th of March, which stipulated only for an “alliance limitée,” had been abrogated by Napoleon’s own act; that Austria had reverted to a position of neutrality; and that, should she take part in the war, it would no longer be in a subordinate character but as a principal. “Le passage de la neutralité à la guerre,” said Metternich to the emperor Francis, “serait l’acte possible qui donnerait par la médiation armée”; which meant in effect that Austria required time to complete her armaments. To gain this time, during the weeks that followed, the object of his diplomacy. For this purpose he encouraged Napoleon to believe that Austria was prepared for a settlement on terms very favourable to the French emperor; with the result that Napoleon, though he would not hear of a “mediation,” not only consented to, but pressed for, Austrian “intervention” (entremise). But Metternich had made up his mind that the only chance of an effective restoration of the Habsburg influence in Europe lay in using this opportunity for destroying or limiting Napoleon’s power, and he had already opened negotiations with the allied courts, with a view to enforcing a common agreement as to a basis of peace, when the indecisive battle of Lützen (May 2) gave him the opportunity of making his policy of mediation effective. Count Stadion was now sent to the emperor Alexander to lay before him the terms on which Austria was prepared to mediate; he was also to “agree to the bases of an active military co-operation on our part, in the event of the non-success of our efforts on behalf of peace.” On the 20th of March Napoleon gained another indecisive victory at Bautzen, which still further strengthened Metternich’s position; for Napoleon allowed himself to be persuaded into signing the ill-omened armistice of Pleiswitz (Poischwitz), on the 4th of June, and to become entangled in the insincere negotiations of the congress of Prague. Austria thus had time to complete her armaments. Meanwhile, on the 14th and 15th of June, were signed at Reichenbach the treaties of alliance between Great Britain, Russia and Prussia, by which the signatory Powers agreed neither to negotiate nor to conclude treaty or truce with Napoleon except by common consent. In an interview with the emperor Alexander, Metternich now presented the terms which he proposed to offer to Napoleon, and on this basis a treaty between Austria, Russia and Prussia was drawn up. One of his aims was to put 150,000 men into the field, should Napoleon reject the armistice, and not to make peace without the consent of Russia and Prussia— which in effect involved that of Great Britain also.

Before this second treaty of Reichenbach was signed (June 27), Metternich went on Maret’s invitation to Dresden, where on the 26th he had the famous interview with Napoleon. The whole scene was on his part a masterpiece of Machiavellian diplomacy. The terms he offered to the emperor were so favourable that he has been denounced by every Prussian historian since as the enemy of Germany; while French historians have enlarged on Napoleon’s infatuation in rejecting them. In spite of the fact that the draft of the treaty of Reichenbach was in his pocket, he posed as the impartial “mediator,” with a leaning in favour of Napoleon, assuring the emperor “on his honour as a German count” that Austria was still “free from all engagements,” which was true only in so far as the treaty was not signed till the next day. Metternich’s object was, in fact, only to gain an extension of the armistice till the 10th of August, so that he and the other allies could be sure that he would be ready to take the offensive. As for the terms offered to Napoleon on his acceptance of them need not hamper the plans of the Allies; for the consent of Great Britain would have to be obtained, and, moreover, Napoleon was sure before long to provide an excuse for a fresh breach; his rejection of them, on the other hand, would be a blow to his waning popularity in France. The interview was long and stormy; Napoleon struggled vainly in the toils; in his excitement he dropped his hat, which the imperturbable Metternich did not condescend to pick up; “Napoleon,” he records in his Memoirs, “seemed to me small.” Metternich, however, gained his immediate point; the armistice was extended to the 10th of August. At midnight on that date, Napoleon not having come to terms, Metternich gave orders for the lighting of the beacons that signalled to the Austrian army in Silesia the outbreak of the war.

Napoleon’s victory at Dresden (Aug. 26 and 27) for the moment brought discord into the counsels of the Allies and threatened the ruin of Metternich and his plans; but the successive defeats of Vandamme at Kulm (Aug. 28), of Macdonald at Katzbach (Aug. 29), and of Vandamme at Grossbeeren (Aug. 30) completely altered the aspect of affairs; and on the 9th of September Metternich signed at Töplitz a treaty with Russia which committed Austria yet more closely to the policy of the Allies. Then followed the battle of Leipzig (Oct. 16-18) and the advance of the Allies into France. The diplomatic situation throughout the campaign was, from the Austrian point of view, one of extreme delicacy. The necessity of curbing the power of Napoleon and rendering him for ever incapable of again oversetting the balance of Europe was practically the only object Austria had in common with her allies. She did not
share the implacable resentment with which Great Britain pursued Napoleon; she watched with alarm the development of the ambitions of Alexander I., which threatened to substitute a Russian for a French supremacy in Europe; she was far from sympathizing with the noisy enthusiasm of the patriots of the War of Liberation for a united Germany, in which the traditional influence of the Habsburgs would be balanced or overshadowed by that of Prussia. Metternich had no wish to see the husband of Marie Louise ousted in favour of the Bourbons, who had little reason to be grateful to Austria; still less did he desire to see on the throne of France Alexander's protégé Bernadotte, whose name was being whispered in the Paris salons as the destined saviour of his native country. But if Napoleon was to remain sovereign of France, it must be not by his own force, but by grace of his father-in-law, and hedged round with limitations which would have made him little more than the lieutenant of the Habsburg monarchy. This was the secret of the moderate terms of accommodation ostentatiously offered by Metternich to Napoleon at various stages of the campaign. From Frankfort he sent, through General de Saint-Aignan, a diplomatist on whose indiscretion he could rely, an informal offer of peace on the basis of France's "natural frontier" the Rhine, the Alps, and the Pyrenees. The "famous manuscript" of Frankfort, issued on behalf of the Allies (Dec. 4, 1813), contained no such offer of acceptable terms; but Metternich's object was attained; for Napoleon refused to be drawn into the trap, and the French people cursed the emperor's infatuation in refusing a settlement which, from what had leaked out of Saint-Aignan's mission, they believed would have satisfied the legitimate ambitions of France. On the other hand, Metternich did his best to oppose a too rapid advance of the allied forces on Paris, which would have played into the hands of Russia and Prussia; and it was to his initiative that the conferences of Châtillon were due. Only when the breakdown of the negotiations made it clear that Napoleon had seen through his plans, and preferred the chances of war to the certainty of ruin or of surviving only as the puppet of Austria, did Metternich join with Castlereagh in pressing upon the tsar the necessity for restoring the Bourbons. On the 1st of March 1814, he set his hand to the treaty of Chaumont, of which the immediate object was the restoration and preservation of the dynasty of France reduced to a puppet of the great Powers in Europe. In other respects, however, the treaty was a triumph for Metternich; for it laid down that at the final settlement Germany was to be constituted as a confederation of sovereign states, and it also did much to temper the fear of a Russian dictatorship by consecrating the principle of that concerted action of the Great Powers, in affairs of international interest, which after Napoleon's fall was to govern the European system. On the 10th of April Metternich arrived at Paris, ten days after its occupation by the Allies. He was now at the height of his reputation; on the 25th of October 1813, two days after Leipzig, he had been created an hereditary prince of the Austrian Empire; he now received from the emperor Francis a unique honour: the right to quarter the arms of house of Austria-Lorraine with those of Metternich. At the same time (Apr. 21) the countship of Daruvan was bestowed upon him. On the 30th of May Metternich set his signature to the treaty of Paris, and immediately afterwards accompanied the Emperor Alexander and King Frederick William on a visit to the French capital.

On the 15th of July he was back in Vienna, where the great congress was to meet in the autumn. The dignity of a Hungarian magnate was bestowed upon him before it assembled.

At the congress Metternich's charm of manner and great social gifts gave him much personal influence; the ease and versatilty with which he handled intricate diplomatic questions, too, excited admiration; at the same time he was blamed for his leaning to intrigue and fineuse and for a certain calculated disingenuousness which led to an open breach with the emperor Alexander, who roundly called him a liar. In the difficult questions of Poland and Saxony the honest and conciliatory attitude of Castlereagh was of more avail in reaching an accept-
was not wholly, or mainly, his. Sir Robert Gordon,1 in a letter to Castlereagh (dated Florence, July 11, 1819), gives the true reason for this attitude: "How much is it to be desired that the superior talents of Prince Metternich were more occupied with the revision and improvement of the administration of affairs in his own country. He is too enlightened not to perceive its most palpable defect... He might have courage to sacrifice himself for the institution of effective remedies, but he fears that the confiding benignity of his Sovereign might afterwards be dissuaded from the just and vigorous application of them." (F.O. Austria. Gordon. Jan.–Dec. 1819.) Metternich's power, after all, was limited by the goodwill of his master, the emperor Francis, and Francis trusted him precisely because he seemed to share his own fanatical hatred of all change. It is this fact that seems to explain Metternich's feverish anxiety to justify his obscurantist attitude to himself and to the world. It suited him to ascribe the general discontent, of which the causes were not obscure, to the wanton agitation of the "sects," and his agents all over Europe earned their pay by supplying him with plentiful proof of the correctness of his contention. The result was well summed up in another letter of Gordon to Castlereagh (ibid. No. 26, Florence, July 12, 1819). "Nothing," he writes, "can surpass Prince Metternich's activity in collecting facts and information upon the inward feelings of the people; with a habit of making these researches he has acquired a taste for them... The secrecy with which this task is indulged leads him to attach too great importance to his discoveries. Phantoms are conjured up and magnified in the dark, which probably if exposed to light would sink into insignificance; and his informers naturally exaggerate their reports, aware that their profit is to be commensurate with the display of their phantasmagoria." The judgment is instructive, coming as it does from a diplomatist in intimate touch with Metternich and in general sympathy with his views.

There was, none the less, method in this madness. Behind the agitations of the "sects" loomed the figures of the emperor Alexander and of his confident Capo d'Istria, "the Coryphaeus of Liberalism," whose agents, official or unofficial, were intriguing in every country in Europe, and not least in Italy. The factor, then, that determined Metternich's attitude was not so much a dread of revolutions in themselves as of revolutions exploited by the "Jacobin" tsar to establish his own preponderance in Europe. Metternich's object, then, in respect of the revolutionary agitations, was twofold: he wished to impress Alexander with the peril of this imperial conspiracy with democratic forces; he wished to convince the "sects" that they could not rely on the "sar's" support. He succeeded in both these objects during the period from the congress of Aix-la-Chapelle in 1818 to that of Verona in 1822. (See Alexander I. of Russia; Europe: History.)

On his way to the congress of Aix, Metternich spent a few days at Frankfort, where his presence was sufficient to settle the difficult question of the constitution of the federal forces. It was a signal triumph. "You can have no idea of the effect produced by my appearance at the diet," he wrote exultingly to his wife, "I have become a species of moral power in Germany and, perhaps, even in Europe" (Mem. iv. 64). This self-complacency was characteristic of the man; but, if we accept his view of "morality," the boast scarce seems exaggerated. In the main questions debated at Aix, indeed, it was Castlereagh's influence rather than that of Metternich which prevailed; the abolition of the supervision of French affairs by the committee of all nations, for instance, carried a general support. But it was at Aix that Metternich was not only reconciled with Alexander, but laid the foundations of that personal influence over the tsar that was to bear notable fruit later; from Aix, too, where he arrived at a complete understanding with King Frederick William III. and the Prussian ministers, dates his preponderant influence in German affairs.

The outlook in Europe at the beginning of 1819 seemed to Metternich particularly gloomy. In France the ministry of Decazes was, in his opinion, under the inspiration of the Russian ambassador Pozzo di Borgo, heading straight for a new revolution; in Italy Russian agents were openly carrying on a Liberal propaganda; Germany, and notably the Prussian bureaucracy, was honeycombed with revolutionary ideas. Then came the news of the murder of Kotzebue (March 23). Metternich was in Italy at the time; but he determined at once to take advantage of this senseless crime to carry his views in the matter of muzzling the Liberal agitation in Germany. In the summer he met King William and Prince Hardenberg at Tölplitz; a conference that resulted in the indefinite postponement of the Russian constitution and in a secret agreement (Aug. 1) on the proposals to be laid before a conference of German ministers to be held at Carlsbad in the same month. The result of this were the famous Carlsbad Decrees (q.v.), by which liberty of speech of the press was abolished throughout Germany. The view of conferences that followed in November and issued in the Final Act of the 15th of May 1820, was not so complete a triumph for Metternich; but his diplomacy, none the less, had succeeded in riveting on Germany the yoke of the Austrian system, which it was to bear with but partial and temporary relaxations for nearly thirty years (see Germany: History).

The year 1820 was marked by critical events which drew Metternich's attention once more from the affairs of Germany to those of Europe at large. The revolution in Spain, with which Austria had no immediate concern, interested him little; but his attitude towards it is characteristic and illuminating. The emperor Alexander for whom the idea of the confederation of Europe was an article of faith, proposed a European intervention and offered to march a Russian army through northern Italy into Spain. Metternich, to whom the remedy seemed far worse than the disease, covered his dissent from this proposal with a great display of principle. The hills of Spain were "moral," those of Europe at large "material"; and the European alliance was there to deal with moral, not material, troubles. The revolution that followed in Naples, however, necessitated a different attitude. Strictly speaking, it concerned Austria alone; but Metternich was anxious to range Alexander openly against Italian Liberalism, and he therefore consented to the question being laid before a congress to be assembled at Troppau. The congresses of Troppau (1820) and Laibach (1821) are dealt with elsewhere (see Europe: History; Italy: History, and the articles v. v.). For Metternich they represented a signal triumph. Not only did he complete his ascendency over the emperor Alexander; but he openly committed all the Powers to an approval of the Austrian system in Italy, a success that outweighed his failure to win over Great Britain to the general principle of intervention enunciated in the Troppau Protocol. His attempt, however, to crown his system in Italy by setting up a central committee on the model of the Mainz commission was defeated at the congress of Verona (1822) by the opposition of the Italian princes headed by the pope and the grand duke of Tuscany.

The sort of moral dictatorship which Metternich had acquired on the continent was shattered by the developments of the Eastern Question. At first, indeed, the peril of a Russian attack on Turkey had drawn Austria and Great Britain closer together, and in a meeting at Hanover in October 1821 Metternich and Castlereagh had come to an understanding as to using the Holy Alliance to prevent Alexander from acting independently of the concert. But Metternich's hope that the Greek revolt would burn itself out "beyond the pale of civilization" was belied by events; and even before Castlereagh's death it was clear that Great Britain would have sooner or later adopted a policy of intervention opposed to all Metternich's wishes. The breach was hastened by the accession to office of George Canning, who hated Metternich and all his ways. At Verona in 1822 the withdrawal of Great Britain from the system of the continental Allies was proclaimed to all the world; in March 1823 Canning recognized the Greek flag. This opened up the whole Eastern Question in the precise form that Metternich had sought to...
avoid; for the action of Great Britain involved a move on the part of Russia, jealous of her prestige in the Levant, and thus led ultimately to a rearrangement of the relations of the Powers which, so far as the integrity of the Ottoman empire were concerned, left Austria isolated. It is impossible here even to outline Metternich’s diplomacy during the eleven years between the outbreak of the Greek revolt and the signature of the treaty of London (1832) by which the kingdom of Greece was established. The principles that guided it are, however, sufficiently simple. In common with Great Britain he desired to maintain the integrity of the Ottoman Empire as a barrier against Russian domination in the Balkan peninsula; he wished also to avert a Russo-Turkish war, not only for the above reason, but also because this would involve the breakdown of the system by which he hoped to curb the revolutionary forces in the West. He therefore attempted, and for a while successfully, to persuade the tsar that the Greeks were only “ordinary rebels against legitimate authority.” But, when this expedient failed, he was the first to suggest the complete independence of Greece, which seemed to him less dangerous to Austrian interests than a triumph of the model of Moldavia and Wallachia. In the end his attitude was one of abstention and protest, since he rightly considered that the action of the Powers which culminated in the treaty of London was fatal to the doctrine of legitimacy, on which his system was based.

The Greek question was not finally settled when the outbreak of the revolutions of 1830 threatened the overthrow of the whole structure of 1815 in the West. Events which seemed to involve the complete ruin of Metternich’s system gave it in effect, however, a new lease of life. Austria, isolated by the events in the East, was once more brought into touch with Russia by a crisis that concerned both Powers equally. On the receipt of the news of the July revolution in Paris Metternich hastened to meet Count Nesselrode at Carlsbad; and, though the Russian statesman refused to commit himself to the idea of an immediate reconstitution of a league of the three autocratic Powers, a common basis of action was agreed upon, and the foundations were laid for that cordial understanding that ripened in the meeting of Münchengrätz three years later. Meanwhile, though his language was still “European,” Metternich’s attitude towards the revolutions was wholly Austrian. He preached the sacred duty of intervention, but he refused to intervene, save where the interests of the Habsburg monarchy were directly concerned. He was even the first to recognize the revolutionary government of Louis Philippe (Sept. 8); he answered the appeal of the king of Holland for help with an ironical reference to the geographical situation of Austria; he did not even interfere with the revolutions in Germany and Poland. But when in Italy revolts broke out that threatened the Austrian hegemony, he acted with promptitude and decision, in spite of the threatening attitude of France; in the spring of 1831 Austrian bayonets restored order in Parma, Modena and the Papal States. Yet even here Metternich showed an unwonted and uncharacteristic desire to encourage the development of Italian nationalism, which he early discerned as the force that might become a menace to Austria itself.

The events of 1832 had not shaken his self-complacency; they seemed to him rather to confirm the soundness of his own political principles, which would have scotched the evil betimes had not the weakness of others allowed the forces of disorder to gather strength. But though, in his own opinion, triumphantly vindicated, he did not again take office; he maintained, none the less, a critical and adviser no mean influence on the councils of the Austrian court, though it was contrary to his advice that Austria signed the treaty of the 2nd of December 1834 with France and Great Britain. He lived to see the beginning of the struggle of France and Italy against Austria, dying on the 11th of June 1859.

Probably no statesman of all time has, in his own day, been more besmirched with praise and bespattered with abuse than Metternich. By one side he was revered as the infallible oracle of diplomatic inspiration, by the other he was loathed and despised as the very incarnation of the spirit of obscurantism and oppression. The victories of democracy brought the latter view into fashion, and to the Liberal historians of the latter part of the 19th century the name of Metternich was synonymous with that of a system in which they could recognize nothing but a senseless opposition to the forces of enlightenment. A juster estimate of the man and his work has, however, become possible as the age has moved farther away from the smoke of controversy. On the whole, history has tended to endorse the sane judgment on Metternich pronounced by Castlereagh when
he was first brought into diplomatic contact with him. Writing from Chaumont to Lord Liverpool, on the 26th of February 1814, he said: ‘Austria both in army and government is a timid Power. Her minister is constitutionally temporizing—he is charged with more faults than belong to him, but he has his full share, mixed up, however, with considerable means for carrying forward the machine, more than any other person I have met with at Head Quarters’ (F. O. 2 France, From Lord Castlereagh). This gives the key to Metternich's character and policy: Austria was a timid Power, and Metternich was an Austrian minister. His policy of “stability,” so necessary for the Habsburg monarchy, at least secured a long period of peace for Europe at large. Europe, her strength renewed, passed a severe judgment on the statesman who acted on the assumption that what the generality of people wanted was peace, not liberty; and justly, in so far as his pessimism led him to convert what might have been legitimate as a temporary counsel of expediency into an immutable principle. But, as it is, the time for Austria to condemn him when Austria shall have survived half a century of constitutional experiment under the dual monarchy.

Of the technique of diplomacy Metternich was a master. His desparches are models of diplomatic style. If they have any fault, it is that they are often over-elaborate, the work of a man who evidently loves diplomacy for its own sake and glories in the fine turn of a phrase. In this respect they are comparable to those of Canning, who modelled himself upon Castlereagh; they are in vivid contrast to the crabbed businesslike letters of Castlereagh. Metternich almost invariably begins his desparches and his reports with a broad discussion of the principles involved in the case in point, and argues from these down to the facts. In this again he is in sharp contrast with Castlereagh, who, with characteristic British practical sense, politely sweeps the principles aside and prefers to argue upward from the facts. In this respect his phrase-making was often the result of astute calculation. His diplomatic genius was never so well displayed as in disguising perilous issues in phrases that soothe even when they did not convince; and, like Gladstone after him, when the occasion demanded it, he was master of the art of appearing to say much in fact he said nothing. When he wished to make his meaning plain, no one could do so more clearly; when he wished to be reticent, no reticence could have been more pleasingly eloquent.

In private life Metternich was a kind, if not always faithful, husband and a good father, devoted to his children, of whom he had the misfortune to lose several before his death. He was three times married. His second wife, Baroness Antonie von Leykam, Countess of Beilstein, died in 1829; his third wife, Melanie, Countess Zichy-Ferraris, died on the 3rd of March 1854. Of his sons three survived him: Richard Clemens Lothar (1829–1867), his son by his second marriage, who was Austrian ambassador in Paris from 1859 to 1871; Prince Paul (1834–1906), and Prince Lothar (1837–1904), his sons by his third marriage. His grandson Prince Clemens (b. 1869), son of Prince Paul, married in 1905 Isabella de Silva Carvajal, daughter of the marquis de Santa Cruz.

Bibliography.—A vast mass of unpublished material for the life of Prince Metternich exists in public and private archives; to some extent it has been given in the memoirs which have been published, but only in the form of letters or notes. The best account of Metternich’s political life is contained in the Memoirs of Anton Proksch-Osten (2 vols., Vienna, 1881); the writings and correspondence of Friedrich von Gentz (q.v.), especially as collected under the title Oesterreichs Theilnahme an den Befreiungskriegen: Wilhelm Oncken, Oesterreich und Preussen im Befreiungskriege (1876–1879); A. Beer, Zehn Jahre österreichischer Politik, 1804 bis 1817 (1877); Die Finanzen Oesterreich (1883); Die orientalische Politik Österreicb seit 1774, (1883); T. T. de Martens, Recueil des traités, &c., vols. iii. and iv.; Thiers, Histoire du consulat et de l’empire, which was frequently commended by Metternich himself as giving an accurate account of his policy, a statement, however, corroborated by Albert Sori, whose l’Europe et la révolution française, gives a detailed and masterly account of Metternich’s share in the overthrow of Napoleon. Fedor van Demelitz’s Furst Metternich und seine auserwählte Politik, vol. i, to 1812 (Munich, 1869), is an elaborate and useful analysis of Metternich’s foreign policy, based on a large mass of unpublished archives. The best short biography of Metternich is that by A. Beer in Der neue Plutarck (1877), vol. v.; but both this and Colonel G. B. Mallison’s Life of Metternich (London, 1888) were written before the publication of the important works of Demelitz and Sori.

METZ, a town, first-class fortress and episcopal see of Germany, in the imperial province of Alsace-Lorraine, capital of (German) Lorraine, on the Moselle, 99 m. N.W. of Strasbourg by rail, and at the radiation of lines to Luxemburg, Coblenz and Nancy, on the French frontier (104 m. W.). Pop. (1905), 30,306. The general appearance of the town is quaint and irregular, but there are several handsome modern streets. The Moselle, which is here joined by the Seille, flows through it in several arms, and is crossed by fourteen bridges. In the south-west corner of the town is the esplanade, with an equestrian statue of the emperor William I, and monuments to Prince Frederick Charles and Marshal Ney, commanding a fine view of the “pays messin,” a fertile plain lying to the south. Of the ten city gates the most interesting are the Porte d’Allemagne, or Deutsche Tor, on the east, a castellated structure erected in 1445 and still bearing traces of the siege by Charles V.; the Porte Serpenoise, or Romer Tor, on the south, and the Porte Francaise, or Französische Tor, on the west. Among its ecclesiastical edifices (nine Roman Catholic and four Protestant churches) the most noteworthy is the Roman Catholic cathedral, with huge pointed windows, slender columns and numerous flying buttresses, which, begun in the 13th century and completed in 1500, is in the Flamboyant Gothic style. The Gothic churches of St. Vincent and St. Eucharius, and the handsome Protestant garrison church, completed in 1851, also deserve mention. Among secular buildings the most important are the town-hall, the palace of justice, the theatre, the governor’s house, and the various buildings for military purposes. The public library contains 40,000 volumes, including an extensive collection of works relating to the history of Lorraine. In the same building is the museum, which contains a picture gallery, a numismatic cabinet, and a collection of specimens of natural history. Metz also possesses several learned societies, charitable institutions and schools, and a military academy. The cemetery of Chambéry contains the graves of 7200 French soldiers who died here in 1870. The chief industries are tanning and the manufacture of weapons, shoes, cloth, hats and artificial flowers. There is a trade in wine, beer, wood and minerals.

As a fortress, Metz has always been of the highest importance, and throughout the period from 1870 it has never succumbed to an enemy, thus earning for itself the name of La pucelle. It now ranks with Strasbourg as one of the two great bulwarks of the west frontier of Germany. The original town walls were replaced by ramparts in 1550, and the citadel was built a few years later. By 1674 the works had been reconstructed by Vauban. Under Napoleon III. the fortress was strengthened by a circle of detached forts, which, after 1870, were modified and completed by the Germans, who treated the fortress as the principal pivot of offensive operations against France. The plans in Fortification and Siegecraft (fig. 43) show Metz as it was about 1900: in the years following a new outer chain of defences was constructed, which extends as far as Thionville on the north side and has its centre in front of Metz on the Gravelotte battleground. The old entrenchment (which includes Cormontagne’s forts) and Moselle and Bellevaux) is doomed to demolition, and has in part been already removed. The garrison, chiefly composed of the XVI. Army Corps, numbers about 25,000. (See Germany; Army.)

History.—Metz, the Roman Divodium, was the chief town of the Mediomatrici, and was also called by the Romans
METZ

Mediately, a name from which the present form has been derived by contraction. Caesar describes it as one of the oldest and most important towns in Gaul. The Romans recognized its strategic importance, fortified it, and supplied it with water by an imposing aqueduct, the remains of which still exist. Under the Roman emperors Metz was connected by military roads with Toul, Langres, Lyons, Strassburg, Verdun, Reims and Trier. Christianity was introduced in the 3rd century of our era. In the middle of the 5th century the town was plundered by the Huns under Attila; subsequently it came into possession of the Franks, and was made the capital of Austria. On the partition of the Carolingian realms in 843 Metz fell to the share of the emperor Lothair I. as the capital of Lorraine. Its bishops, whose creation reaches back to the 4th century, now began to be very powerful. Metz acquired the privileges of a free imperial town in the 13th century, and soon attained great commercial prosperity. Having adopted the reformed doctrines in 1532 and 1553, it fell into the hands of the French through treachery, and was heretically and successfully defended against Charles V. by Francis duke of Guise. It now sank to the level of a French provincial town, and its population dwindled from 60,000 to about 22,000. At the peace of Westphalia (1648) Metz, with Toul, Nancy, and Remaches, was formally ceded to France, in whose possession it remained for upwards of two centuries. The battles of August 1870, and the investment and capture of the army of Metz which followed, are described below. By the peace of Frankfort on the 9th of May 1871 Metz was again united to the German Empire.

Battles around Metz, in the Franco-German War, 1870

1. Colombey-Borny (August 14).—The French army under Marshal Bazaine was in and about Metz. The German I. and II. armies, on the march from the Saar, were heading for the Moselle between Metz and Pont-à-Mousson, and on the morning of the 14th of August the German I. Army (I., VII., and VIII. Corps, under General v. Steinmetz) lay on and east of the French, with outposts well to the front, watching the French campaign of the preceding days, and having just started the advance. Steinmetz had received from headquarters overnight instructions that on the 14th of August the I. Army would maintain the positions occupied during the 13th, and merely pass on these orders to his corps commanders. In Metz, meanwhile, Bazaine had decided to retreat, and during the morning orders to that effect reached his corps commanders, who commenced preparations for their execution. The 2nd Corps (Frossard) and 6th (Canrobert) began to retire about midday, the 3rd (Lebecq), 4th (Ladmirault) and Imperial Guard (Bourbaki) were to follow. These preparations being observed, the German outposts got under arms. General v. der Goltz, in command of the VII. Corps (7 battalions, 4 squadrons, 2 batteries), hearing from a passing officer that the I. Corps on his right was preparing to attack, and noting personally signs of retreat in the enemy's lines, determined at 3 p.m. to advance his whole command to the ridge between Colombey and Borny (which was still occupied by French outposts), in order to clear up the situation. The ridge was captured with little resistance, but the sound of the firing at once brought up the neighboring troops in military formation, and so, for the French, had immediately retaliated on von der Goltz's audacious attack. Between 4 and 6 p.m. there was continuous heavy fighting on the front from Borny to Médy, as both sides brought fresh troops into the field. The convex slopes falling from the Prussian position towards Metz gave plenty of cover to the French, and the setting sun shone full in the faces of the Prussian artillerymen. Thus the Prussian infantry encountered unusually obstinate resistance and the troops engaged rapidly slipped from all superior control. The above front was held by the French 3rd Corps. Shortly before 6.30 the 4th Corps (Ladmirault) suddenly began to deploy on the high ground to the north-west beyond Médy, thus threatening the right flank of the Prussian I. Corps (General v. Manteuffel). To meet this danger Manteuffel was compelled to direct his corps artillery and reserves, which were now rapidly coming up, away from the hard-pressed centre towards the oncoming infantry forces of Ladmirault. These, with the sun now almost at their backs, were shooting better than usual, and Manteuffel was compelled to call on the VIII. Corps for assistance, which its commander, under positive orders from Steinmetz, refused to give. Meanwhile Steinmetz had been sending peremptory orders to the battlefield to stop the battle, but neither of the corps commanders was able to enforce them. Fortunately for the Prussians, Bazaine had issued similar orders to his subordinates, who, having their men better in hand, were able to obey; and as night began to close in the French broke off the action and retired under the guns of the Metz forts, convinced that at last they had "broken the spell" of German success.

Finding that, in spite of his orders, the firing at the front continued increasing in intensity, Steinmetz at length rode to the front himself. Meeting Manteuffel near the Brasserie of Nogent-le-Vieux, he asked: "Is that the end of the matter?" To which the Prussian answered: "This is the last round of the evening." In this action the Germans brought 30,500 rifles and 150 guns on to the battlefield only out of more than 100,000 with 300 guns which could have been engaged before darkness. Bazaine actually deployed 50,700 rifles and 206 guns to oppose them. He might, however, had he been so minded, have struck with his whole army—nearly three times this force, and, judging from the course events actually took, we can have little doubt as to the result of such a blow. The losses on either side were in killed and wounded—French about 3600, Germans about 4800.

The chain of causation in this action is particularly worthy of attention: A young reserve officer, seeing some troops of the I. Corps standing to arms, reported to von der Goltz that the corps was standing to arms and about to attack. Von der Goltz thereupon decided to go forward and discover what was actually going on, and this action unchained the whole battle power of all the troops within call. When, on the following morning, Steinmetz reported von der Goltz and the commander of the I. Corps for disobedience, the king thanked Manteuffel warmly for the part he had played, and thus comforted the Prussian brigadier who had disobeyed orders and congratulated him on having twice distinguished himself in the first fortnight of the war.

2. The Battle of Vionville—Mars-la-Tour (August 16).—On the following day (15th) the II. German Army approached the Moselle above and below Pont-à-Mousson, with a view to overtaking and heading off Bazaine in his presumed retreat to the Meuse (see FRANCO-GERMAN WAR). So far, however, from being ahead of the Germans on the road to Verdun, the French were actually late in the afternoon of the 15th of August, bivouacked on the plateau of Rezonville, and there their outposts were placed, not where they could see the surrounding country, but at the regulation distances of 600 to 1000 paces from the bivouacs. Friendly inhabitants kept Bazaine well informed as to the magnitude of the danger threatening him from the south, and a special telegram from Paris, the true origin of which has never been traced, led him to believe that the I. German Army was crossing the Moselle near Thionville and about to descend on him from the north. This telegram misled the commander of the I. Corps, who supposed the whole course of the battle had not Ladmirault (4th Corps), nearer to the seat of the imaginary danger, taken upon himself to disregard the warning transmitted to him by headquarters. At daybreak on the 16th, no Prussians being reported in sight by the outposts, the troops began nonchalantly to prepare for the resumption of the march.

On the Prussian side, von Alvensleben's Corps (III.) shortly after daybreak was moving north-westward from the Moselle in two columns, on the right the 5th division, via Gorze and Flavigny on Vionville, on the left the 6th division with corps artillery by Arnaville on Mars-la-Tour, von Alvensleben himself riding
a little in advance between the two. The 6th cavalry division was ordered to precede the right column and scout towards Rezonville. No one was aware of the dangerous proximity of the French army.

About 9 a.m. the 5th cavalry division, reinforced by two horse artillery batteries (flank guard of the X. Corps from Thioncourt), and accompanied by von Caprivi (chief of staff, X. Corps, and afterwards chancellor of the German Empire), were trotting up the western slopes of the ridge which runs between Tronville and Vionville. Reaching its summit they

suddenly found themselves in face of at least 40,000 French troops, which were not under arms, but busy with miscellaneous camp duties. The temptation proved too great for the artillery, who promptly fired into the midst of the cavalry camp (Forton's division) which lay nearest to them. The momentary result was a wild panic, especially among the horses; but this panic gave the alarm to the infantry all along the road, and these (Frossard's 2nd Corps) at once stood to arms and moved forward, deployed for attack—one division to the west, another division, from Rezonville, to the south. The latter almost at once encountered the heads of the 6th cavalry division, at that moment just clearing the defile leading up to the Rezonville plateau from Gorze. The Prussian cavalry promptly bore away to cover to the westward, and reported what they had seen to superior authority, but not to the advanced guard of the 5th infantry division, which, emerging in its turn from the defile, ran right against the deployed French infantry moving to meet them. So sudden was the collision that the Prussian advanced guard battery had to fire case to clear its own front.

Meanwhile von Alvensleben himself, riding on the field track from Gorze towards Vionville, whence he could overlook the whole country to the north and west, had met von Rheinhaben (commanding the 5th cavalry division) and had seen the surprise of the French camps. The sound of the heavy firing coming from the eastward convinced him of what had been gradually dawning on him—that with barely 20,000 men he was in the presence of the whole French army, whose attitude at this moment sufficiently indicated their determination to fight.

In a few moments his decision was taken. Calling on the X. Corps, away to the south-westward, for support, he determined to screen his own weakness by a vigorous attack. By universal consent this is approved as the boldest resolution arrived at by an independent commander throughout the war. Orders were forthwith despatched to the 6th infantry division, at that moment between Puxieux and Tronville, to wheel in to their right and attack, and, their movement being still hidden from the enemy, these troops were formally drawn up for action and sent forward as a whole. The French meanwhile had occupied Vionville and Flavigny, and other troops were moving down the slopes from Rezonville to their support, but the united onset of this whole German division overbore all resistance, and the French began to retire eastward, suffering terribly from the shell fire of the Prussian batteries.

Marshal Bazaine had meanwhile arrived on the scene, and ordering forward fresh troops to relieve (not to reinforce) those already engaged, he rode forward with a horse artillery battery to watch the operations. The retreating French troops belonged to Frossard's command, and as they were in considerable confusion Frossard called on du Preuil's brigade of the imperial guard cavalry to charge. He gave no objective, and when the
brigadier pointed out that the enemy was still beyond the striking radius of his horses, Frossard reiterated the order, which was obeyed to the letter.

The result was disastrous. The Prussians, having seen the cavalry whilst yet at a distance, ceased firing, formed their skirmishers into groups, and the closed supports standing in deployed lines, two deep, shattering the cavalry with volleys and file-firing, as with blown and exhausted horses they endeavoured to close with their adversaries. When in addition two hussar regiments struck them in flank they were driven back in wild disorder upon Rezonville. In the dust and confusion of the charge a group of the hussars approached Bazaine and his horse artillery battery, and almost carried off the marshal.

Alvensleben, mistaking the withdrawal of the French for the beginning of a retreat, had meanwhile sent orders to the 6th cavalry division to charge in pursuit towards Rezonville; but before it could reach the field the French relieving troops had forced their way through the stragglers and showed such a bold front to the Prussian horsemen that an attack held no promise of success, more especially since they had lost their intervals in their advance and had no room for a proper deployment. To steady the young soldiers, the cavalry commander (Carl von Schmidt) halted his men, made them correct their intervals and dressing as in peace, though under a heavy fire from the French infantry, and then withdrew them behind the cover of the nearest hill at a walk.

The threat of the charge had, however, induced caution on the French side, and for about two hours there was a lull in the fighting, which the Prussians utilized on their right in bringing up reinforcements through the Bois des Ongons. On their left, however, no fresh troops were as yet available, and when being informed, about 2:30 p.m., that French cavalry seemed to be about to charge the exhausted 6th division, Alvensleben ordered Bredow's cavalry brigade to charge, and if necessary to sacrifice itself, to save the infantry. Bredow's command (six squadrons of the 16th Ulan and 7th Cuirassiers) was at that moment drawn up under cover about half a mile west of Vionville, and from its position could see nothing of the events in progress on the battlefield. Netted by the form in which the order was conveyed to him, Bredow drew his sword and ordered his trumpeter to sound the "trot," the brigade moving off in line of squadron columns at close interval in the direction in which they happened at the moment to be facing. Near Vionville they took ground to their left, opening to full intervals as they did so, and then ascended the gentle incline which still hid them from their enemy.

Arrived at the summit, Bredow sounded "line to the front," but at that moment a storm of French bullets swept down on them, and the men, no longer to be restrained, dashed forward, before the line could be completed, almost due east against long lines of infantry and artillery which they now saw for the first time about 1,200 yards in front of them.

This distance was covered at the fullest extended speed of the horses, and reaching the infantry they swept over them "like hounds over a fence"—in the words of an eyewitness. So sudden had been their onset that very few were hit until the infantry had been passed; then the latter, recovering from the shock, turned and fired into the cavalry from behind, whilst a fresh division of French horsemans charged them in flank. After a desperate mêlée of some minutes, the rally was sounded, and the survivors of the charge, breaking their way a second time through the French infantry, eventually reached the shelter of their lines, having lost rather more than half their number, but having saved the situation momentarily for their own army. Again there was a lull in the operations.

Meanwhile, unknown to Alvensleben, a fresh storm was brewing on his left rear.

Ladmirault, commanding the French 4th Corps had seen, during the afternoon of the 15th, the terrible crowd and confusion prevailing in the defiles leading to Gravelotte, and resolved to disengage his orders and to move direct from his bivouacs by the road from Woippy to St Privat, disregarding altogether the alleged danger from the Prussians supposed to be advancing from Thionville. Thus, about noon on the 16th he reached the high ground between St Privat and Amanvillers, and still without instructions he determined to direct his corps on Bruvill and Doncourt, whence he could judge from the drift of the smoke-clouds whether he could fall on the Prussian left.

Much time was lost owing to the heat of the day and the fatigue of the troops, but shortly after 3 p.m. he reached a position north of the Tronville copses whence his guns could fire into the left rear of the long line of Prussian guns (6th division and corps artillery) on the heights above Vionville and Flavigny. Their fire threw the latter into serious confusion and he had already decided to attack with his nearest division (de Cisy) in the direction of the steep of Vionville, when his attention was caught by the outbreak of heavy firing in the copses and the entry of fresh Prussian guns into action.

This diversion was brought about by the arrival of the corps artillery of the X. Corps and of the 40th division, which latter had been at once ordered into the Tronville copses to check portions of Tixier's division of the French 3rd Corps, which under cover of these copses had gradually worked round the Prussian flank. Seeing then that the troops before him could hold their own, Ladmirault continued his preparations for his counter-stroke, and Cisy's division had begun to move into its prescribed alignment, facing towards Vionville, when the sudden appearance of a closed mass of Prussian troops detached itself from the low dust-cloud of a slow-moving infantry column, and forming to the south of Mars-la-Tour, again arrested his attention. Unanimously he and his staff agreed that this fresh enemy could only be the advanced guard of a large Prussian force, possibly, it was suggested, of the crown prince's army, from Alsace and Nancy, and a fresh delay arose while the situation was investigated. Actually this body consisted only of the 38th division (von Wedell), forming part of the X. Corps. It had no knowledge of the state of affairs on the battlefield, or in the direction of Bruvill, though Prussian cavalry had been observing the approach of Ladmirault's corps for some hours. It was now ordered to deploy and to co-operate with the 40th division in an attack on the Tronville copses. This meanwhile had been delivered, and had more or less failed.

The deployment completed, about 4 p.m. the 38th division began its advance on the north-west corner of the Tronville copses, this direction taking them diagonally across the front
of Cissey’s division, still out of their sight but moving due south. Hardly had they stepped off when Cissey’s first line, catching sight of them, opened a devastating fire upon their left flank, and to meet this fresh danger the Prussians endeavoured to change front half-left whilst still on the move. Without pausing to fire, the men raced onward, but the French striking their outer wing rolled up the whole line in succession, the actual collision occurring in and about the Bruvillais ravine, a deep-cut natural trench which, starting from the Tronvils copse, here intersects the plateau from west to east. Against the weight of French numbers, nearly three to one, the Prussians were unable to stand, and presently they broke and drifted backwards, completely routed. Then the second Guard Dragoons (since known as Queen Victoria’s regiment), after a brilliant maneuvre under heavy fire, to get into the best position for delivering a charge, rode down the whole French line of pursuers from left to right, and by their heroic self-sacrifice relieved the remnants of the infantry from further pursuit.

This was the scene which for the moment held the attention of Prince Frederick Charles when at length he reached the battlefield from Pont-a-Mousson. All along the rest of the line the Prussians were still holding their own, and on the extreme right fresh troops from the IX. Corps were streaming up through the woods against the French left wing. But on the left there was every sign of incipient disaster, and to avert this only the cavalry were at hand. Sending, hastily orders to the 5th and 6th cavalry divisions to concentrate to the west of Mars-la-Tour, the prince ordered them from there to sweep round on the right rear of the French army. The same idea had, however, occurred to Lamirault, and he had called on the two nearest French cavalry divisions to put it into execution, and as the Prussians began to reach the plateau west of Mars-la-Tour and the Yron brook from the south, the French were deploying across it some two thousand yards to the north.

Thus began the duel—the one great cavalry duel of the war—between upwards of two thousand horsemen a side. But it was delivered by both sides in a series of regimental charges, and in result was singularly indecisive. For about half an hour great crowds of riders, hidden by dense clouds of dust, drifted aimlessly about the plain, till at length the charge of a single squadron of the Oldenburg Dragoons (who had joined in on their own initiative) delivered on the outer French flank, brought the whole mass into motion north-eastward, and, both sides sounding the rally, the engagement gradually ceased.

It was now about 7 p.m. and night was coming on. Seeing the dust-clouds drifting away northward, and noting the lethargy which seemed to have settled over the whole French line, Prince Frederick Charles decided to assert his own independent will to conquer by a final assault along his whole front. Guns, cavalry, infantry, everything that could still stand were to take part in it. Weary as they all were, his indomitable will put fresh life into the whole army. With drums beating and colours flying, every unit within call went forward for the final effort. It was almost dark when the Prussians approached the French position between Rezonville and the woods to the northward, and the troops soon lost direction in the smoke and became involved in the direst confusion; the firing again blazed out for a few moments, only to die away as utter exhaustion at length put an end to the Prussian advance. Then the wearyied troops, for the most part, lay down and slept in the positions they had reached.

Thus closed the hardest fought battle of the Franco-German War. From 9 a.m. to 3 p.m. only 23,700 rifles, 8,100 sabres and 126 guns had been brought into action by the Germans against 59,100 rifles, 6,700 sabres, and 300 guns on the French side, and even at the close of the day the former had only deployed 47,100 rifles, 8,300 sabres and 222 guns against 83,000 rifles, 8,000 sabres and 422 guns including 24 mitrailleuses. The chief characteristic of the day’s fighting was the terrible effectiveness of the Prussian artillery, which was handled in masses and not, as on the French side, by batteries. The manoeuvring power of the latter attracted the admiration of the Germans, but arriving singly on the field they were generally reduced to silence in a few minutes. Deprived of their support, not all the gallantry of the French infantry could avail anything. Again and again, particularly on their left wing, they chased the German infantry before them, but the moment the retreat of the latter downhill uncovered the pursuing French to the Prussian guns, a tornado of shells shattered their order and compelled them to retreat.

Though the cavalry were freely engaged, the training of both was so far beneath the standard of the present day that the most that can be credited to them in respect of results is that they from time to time averted imminent disaster, but failed altogether to achieve such a decision as was well within their potential capacities.

3. Gravelotte—St Privat (August 18)—The position on to which the French army fell back from the field of Vionville is formed by a ridge some six miles long running from Rozerieules almost due north to Roncourt, a little village overhanging the steep and wooded banks of the Orne, and connected with the general plateau between the Meuse and Moselle by a gentle saddle running from about Amanvillers nearly due west through the Bois de la Cuise towards Doncourt. North of this saddle the slopes show a slight concavity, but are passable by troops of all arms in close order. To the south the rivulet of the Mance soon forms a formidable obstacle as its bed cuts its way through the sandstone. Scrub and woods with dense undergrowth line both its banks, and, except by the great caussée from Metz to Verdun, access to the French side becomes impossible to troops in ordered bodies.

It does not appear that the position had been systematically examined, or apportioned to the several corps in accordance with any predetermined plan. The army merely swung backwards, pivoting on its left wing, the corps preserving their relative order as it had been on the 16th, with the exception that the Imperial Guard was withdrawn to the spur on which Fort Plappeville stands, and the 6th Corps (Marshal Canrobert) crossed the line of march of the 3rd and 4th Corps in order to gain St Privat la Montagne. No lines of march were assigned to the several units, consequently the confusion became so great that though the distance to be traversed in no case exceeded six miles, only the right wing and centre reached their destinations as night was falling. Many of them had so little idea of the general situation that they actually placed outposts to the north and east, whilst the whole of the enemy’s army lay to the south and west. No attempt was made to entrench the position systematically, but on the left the 2nd and 3rd Corps made some disconnected shelter trenches and gun-pits, while the 4th Corps in the centre began to improve available cover about an hour before the battle began, and the 6th corps on the right, not yet having received any entrenching tools, could do no more than improvise a few loopholes in the walls of the villages of St Privat and Roncourt with such tools as the sappers could obtain from the inhabitants.

Fortunately for the French the Germans were too exhausted by the battle of the 16th to attempt to interfere with these movements. At daybreak on the morning of the 18th the royal headquarters (which now for the first time arrived at the front) still had no certain knowledge as to whether the French main army was in retreat—covered by the force which they could see on the high ground north of the Metz road—or whether they had taken up a position in order to fight.

Hence the orders issued overnight on the presumption that the main force of the French was retreating to the north and west were allowed to stand, and the whole II. Army (Prince Frederick Charles) moved off in echelon from left to right, the I. army under Steinmetz, consisting for the day of the I., II. and VII. Corps, being left in observation of the troops visible on their front and of the garrison of Metz itself. The I. Corps was kept back beyond the Moselle on the east side of Metz, the II. was not due to arrive at Rezonville before 4 p.m., hence the VII. only was immediately available if the enemy counter-attacked. But Steinmetz had not ordered, nor had von Zastrow, the corps commander, undertaken, any preparations to meet an emergency.

About 10 a.m. the corps had reached the following positions:
VIII. Corps, Rezonville; XI. near St. Marcel; Guard approaching Doncourt; XII. towards Jarny; the III. and X., which had been so heavily engaged on the 16th, still in their bivouacs preparing to move. The cavalry of the Saxons had established the fact that the French had not retreated northward, but though scouts from the Guard had already seen the enemy on the heights of St Privat, this information had not yet reached headquarters, nor had it been transmitted to the IX. Corps, which it most closely concerned.

Shortly after 10 a.m. Molike, still under the impression that the French right extended no farther than La Folie (2 m. north of the Metz road), determined to attack with the IX. and VIII. Corps whilst the Guard executed a turning movement via Habonville against the French right. The IX. Corps was to engage, but not to push its attack home until the Guard could co-operate. The XII. Corps was left to its own devices, but fortunately the crown prince of Saxonoy, who commanded it, had ridden forward and, seeing the French in force towards Roncourt, had issued orders which in the event proved decisive.

In pursuance of his instructions von Manstein, commanding the IX. Corps, set his two divisions in motion towards La Folie and the Bois de la Cusse, and advanced to reconnoitre the French position. From the eastern edge of the above-named copes he suddenly descried the camp of a whole French Corps (the 4th), evidently ignorant of their danger, on the slopes trending westward from Amanvillers. Unmindful of the experience of the 16th, he decided to execute an artillery surprise on a grand scale, and sent orders to his corps artillery to come into action on the long spur overlooking the French camps from the westward. At noon, just as the French infantry were falling in for midday roll-call, sufficient guns were in position, and suddenly opened fire. But the effect was disappointing. The French infantry ran to their arms, piling along the front of their positions, and moved forward to attack, covering their advance by a hail of bullets. Simultaneously the French artillery also took up the challenge, and from the heights near St Privat the 6th Corps, whose presence had been unsuspected by the Prussians, joined in the fight.

In a few minutes the batteries on the extreme Prussian left were completely overwhelmed, and suddenly dense lines of French skirmishers emerged from a fold in the ground upon their flank and front, and the gunners were compelled to resort to case-shot, so imminent was their danger. But at this critical moment the leading companies of the Hessian infantry arrived, re-established the equilibrium (though not before four Prussian batteries had been temporarily overrun by the enemy), and a most obstinate fight ensued.

Prince Frederick Charles now rode forward to a point north-east of Vernéville, whence the southern boundary of St Privat could be seen. But the northern side of the village and the country towards Roncourt was hidden from his view by the high poplars bordering the Metz-Briey road. Seeing the Hessians hard pressed, he now brought forward the 2nd division of the Guard to their assistance, sending in the 3rd brigade immediately, and holding the 4th brigade in reserve. The 1st division, worn out by their own scouts and by the French troops in Ste Marie, deployed to attack this village, and were assisted in their endeavours by a brigade of Saxons detached by the crown prince of Saxony, who from his position could see behind the poplar screen that limited the view of the commander-in-chief. Hence he was already aware that the French position extended to Roncourt at least, and had despatched a whole division down the valley of the Orne to outflank them. No news of this movement, however, appears to have reached Prince Frederick Charles.

The French troops in Ste Marie were only an outpost of the 6th corps, and seeing themselves outnumbered, they withdrew about 2.30, the Prussians rushing the village immediately afterwards. Considerable confusion arose from the convergence of these three brigades upon one village, and more than an hour passed before the troops could be disentangled and massed for further operations. The leaders of the two Guard brigades, still ignorant of the extent of the French position, rallied their men on the main bodies of their commands (which had not been engaged) and then lined up facing exactly as they had done when brought forward to the attack. Thus the 1st brigade lay, facing about east-south-east, south of the chaussée and some five hundred yards west of the village. The 2nd brigade lay south-west of the village about three hundred yards away from it and facing nearly north-east.

The Saxons were on the left rear of the 1st brigade, but took longer to recover themselves than the Guards. With the Hessians and the IX. Corps the action still dragged; the 3rd brigade of the Guards had become involved in the fight, and notwithstanding the arrival of the corps artillery of the III. Corps in the centre the situation was still critical. From the south also came the thunder of guns and no encouraging news from that quarter had as yet reached the prince's headquarters.

About 4.30 p.m. the prince therefore had to consider how long it would take to obtain a decision. To postpone it till the morrow seemed undesirable; to achieve it before nightfall was only possible at the cost of immediate effort.

He therefore decided to assault St Privat with all the Guards available, and called up the III., X. and Saxons to assist him.

The 4th brigade of the Guards now received their orders to attack Jérusalem (a hamlet a little south of St Privat), and the 1st division was ordered to assault St Privat itself.

Von Pape, commanding the latter division, pointed out that no artillery force adequate to prepare the way for him was as yet on the ground, and that the Saxons were still a long way to the rear. But his orders were imperative, and the 4th brigade was already moving off and had to be supported at any cost. Actually all available batteries had already been sent for and were trotting forward from every quarter towards the objective. He accordingly transmitted his orders, and the 2nd brigade was the first to attempt their execution.

It had to wave half-right in mass to bring it in the required direction, and then to advance till its rear was clear of the obstruction formed by the gardens of St Marie. By the time (5.30) it had sufficiently cleared this village it became apparent that the 4th brigade in its extension for attack would overlap the front assigned to the 2nd, hence a further (half-left) wheel, still in mass, had to be undertaken before room for deployment could be obtained. Almost as the commands were given, the French suddenly opened an overwhelming long-range fire and their bullets swept like hail through the crowded mass of the German troops. Nevertheless the wheel was effected, the fresh direction taken, the troops extended for attack, and then the whole brigade dashed towards the houses assigned them as their objective. Meanwhile the 1st brigade had moved round the north of the village and carried out its extension without serious hindrance. But emerging from the hollow running north from St Marie, they came under a heavy fire not only from St Privat but also from Roncourt, which latter village they now saw for the first time. Instinctively a portion of their line worked to the left to face this new menace, and the front thus became dangerously extended. They were, however, within a few hundred yards of the rear of the 3rd and 1st brigades, and the whole line raced forward to reach the objective, thus breaking out of the many inferior weapons, which were about equal at 200 yds. to the French rifle at 600. But the losses of the 2nd brigade, particularly in officers, had been too heavy, and the rush died out whilst still 500 yds. from the two villages.

It was now about 6 p.m. and a long pause ensued, while the 220 guns, which by degrees had limbered behind them, brought St Privat and Roncourt under fire. About 7 p.m. the Saxon turning-movement took effect; their infantry from the Orne valley attacked Roncourt from the north, and about 7.15 the village was carried.

Neither Prince Frederick Charles nor the troops in the fighting line could see what had taken place, but the former seeing other Saxons moving towards Montois and the masses of the III. and X. Corps approaching, whilst the rain of shells into St Privat exceeded anything hitherto seen on any battlefield, decided to call on the whole of his force to attack. He was in
the act of issuing his orders when a psychological wave swept through the fighting-line, and the men rose and rushed the village at the point of the bayonet. It was now about eight o'clock, and the light was rapidly failing.

The French artillery had already evaded the coming blow, and had changed position, “right back,” to cover the flank of the rest of the army, and the Prussian and Saxon artillery trotting forward conformed to this new front, their shells sweeping the ground for 2000 yds. to the south of Amanvilles. The confusion in and around St Privat, where troops from four several corps were all intermingled, became so extreme that no further infantry-advance could be attempted; so under cover of the fierce artillery duel the remnants of the unfortunate 6th corps drifted away towards Metz down the many ravines leading into the river valley. The “annihilation” of the Guard at St Privat has become historic. Yet, heavy as were the losses of the 1st Guard division they were not excessive compared to those suffered, and in round numbers one-third of their effectives had fallen—most of them in the first great rush forward at 5.30 p.m.; but actually they had been more or less under fire since about 2 p.m., and many were hit by French shells plunging into the turmoil about St Privat from 8 to 10 p.m. But the legend cannot be justified when the facts are compared with the slaughter of the Seven Years’ War, of Napoleon’s battles, the Crimea, and the American Civil War, or with the horrible punishment of von Wedell’s brigade (38th) only two days before.

It is now time to return to the southern theatre of the battlefield, where an entirely independent engagement had been raging all the afternoon. Von Goeben with the VIII. Corps was standing massed about Rezonville when von Manstein’s guns opposite Amanvilles suddenly made themselves heard. Wheeling his corps to face the French to the eastward he immediately sent forward his artillery and prepared to support his command with the VII. Corps followed his example. Both corps took as their primary objective the farms of St Hubert and Point du Jour, standing just above the defile made by the Verdun-Metz road where it climbs out of the Mance ravine towards the French position. About 3.30 p.m. St Hubert was carried by a confused mass of some 49 companies, and von Steinmetz, believing the main French position to have been pierced, ordered the 4th cavalry division to cross the ravine by the chaussée and pursue. Simultaneously von Zastrow, under the same impression, had ordered his corps artillery to advance by the same road, and von Goeben, thinking his troops in front required support, had sent forward an infantry brigade by the same line of road.

Presently all these columns converged upon the defile and a hopeless entanglement ensued. Three batteries succeeded in struggling through the mass, and, in coming into action, their left resting on St Hubert, but the remainder of the troops had to be withdrawn, and confusion breaking out in their rear, exposed to all the random bullets and shells of the French, a panic ensued, thousands of men breaking away and flying in wildest confusion through Gravelotte towards the west. Hardly had they melted away when the French made a most brilliant counter-attack from their main position between the farms of Leipzig and Moscow. This was stopped almost entirely by the Prussian artillery fire; but the news of its coming spread through the stragglers in the ravine south of the great road, and a wave of panic again swept through the mass, many thousands bolting right upon the front of their own batteries, thus masking their fire at the most critical moment, and something like a crisis in the battle arose. Fortunately the II. Corps was now rapidly approaching (about 6 p.m.), and the king, against von Wedell’s advice, now ordered von Steinmetz (to whom the II. Corps had been allotted for the day) to attack again with all his forces. Meanwhile a third panic broke out which delayed the preliminary movements and it was now growing dark in the ravine. At length the II. Corps, together with all of the VII. that could be collected, moved down into the valley. Just as the leading German troops were approaching St Hubert the French again began to fire, their bullets plunging down among the fresh arrivals, who knowing nothing of what had taken place about St Hubert (where the remnant of their own infantry were still offering a desperate resistance) opened fire into the backs of their own men, and a fourth panic began which soon spread to the stragglers crowding the Mance ravine. Fortunately, by the superb gallantry of some of the company officers and men, the new arrivals were induced to recognize their mistake, and by degrees about 10 p.m. the whole of the II. Corps succeeded in reaching the plateau between St Hubert and Point du Jour, where the débris of the VII. and VIII. Corps had gathered. But in the darkness and confusion no forward movement against the French (only 400 yds. to their front) could be initiated, therefore the whole mass passed the night where they stood until daylight disclosed that the French had retreated.

Meanwhile the King, Molitke, and Bismarck, had ridden back behind Gravelotte where they passed two hours of intense anxiety. From the flash of the rifles, it was clear that the French main position was still intact, and as every body of troops within thirty-six hours’ call had been engaged there seemed little prospect of renewing the struggle next morning. No news too had come in from Prince Frederick Charles. Ultimately about midnight the welcome tidings of the capture of St Privat arrived, and all anxiety was at an end.

4. The Investment of Metz (Aug. 19–Oct. 14).—During the night following the battle of Gravelotte the French army withdrew within the line of the forts round Metz. The 6th Corps only was severely shaken, the 4th (the best in the whole army), though it had fought hard twice within forty-eight hours, losing nearly 30% of its strength, was still well in hand, and the 3rd, 2nd and Imperial Guards were almost intact. A fresh issue of ammunition and food was all the French could do to make them a thoroughly efficient fighting force comprising some 100,000 troops, capable, with a resolute leader and an efficient staff, of crossing over to the right bank of the Moselle, overrunning the I. German Corps, the only one in their direct path, and then fighting their way across the communications of the II. and III. German Armies until they regained touch with the French railways to the south-west about Troyes.

The mere fact of the effort being made would have given the battle of Gravelotte the moral effect of a victory, and the reaction in the German ranks from the feeling of over-confidence, which had mastered them after the early successes of Spichern and Woerth, must have had most far-reaching consequences.

Bazaine, however, withdrew entirely under cover of the forts, and set about the reorganization of his troops in the most leisurely manner. The Metz forts, though neither sufficiently armed nor even completely finished in some cases, were nevertheless with their deep ditches and self-protection bastion trace, far too formidable for any field army to attempt without the aid of a siege train of some 200 guns, which for the moment were not available. Of this fact the Germans were well aware, and hence they decided from the first to reduce the place by hunger, calculating that with the extra 150,000 men thrown back upon the fortress, its food supplies could not last very long. On the morning of the 19th the German army was far too exhausted for further efforts. Except the I. Corps, which had been summoned overnight from its position about Courcelles towards the battlefield of Gravelotte and had almost reached the Moselle before this move could be counterordered, the remainder kept their places of the previous night, only following the French retreat with a screen of outposts. They were sufficiently occupied in collecting the wounded and clearing up the confusion resulting from an accumulation of trains and transported in the defiles of Gorze and about Novéau. No eastward movement could have taken place that day. In the course of the afternoon of the 19th the royal headquarters, creating a new army under the crown prince of Saxony (Guard, IV. and XII. (Saxons) Corps) for field operations towards the Meuse, assigned the remainder of the II. Army, and the whole
of the I., to Prince Frederick Charles as commander-in-chief of the army of investment. This brought the strength of his command up to eight corps, numbering some 220,000 men, an enormous mass to feed in a district swept bare of supplies by the operations of the preceding week, and with only one railway line, terminating at Courcelles, to depend upon.

For the moment the chief care of the Prince was to guard against an attempt of the French army to break out to the westward. The I. Army Corps with Kummer's Landwehr division (which arrived during the night of the 19th-20th of August) were to occupy a position to cover the rail head at Courcelles-Rémiilly, and the remainder were disposed in the following order: The X. Corps was on the north, with a bridge head at Hauconcourt-sur-Moselle, the II., VIII., and VII. following along the eastern slopes overlooking the Moselle valley, the latter having also a fortified bridge head at Ars-sur-Moselle. The III. and IX. were cantoned almost on the battlefield of the 18th, between Caubre Farm and Roncourt, ready to move off to the left and support the X. Corps in the event of an attempt on the part of the French to break out towards Thionville.

The positions were fortified with a light outpost line, behind which was drawn a main position on which every art of the engineer was expended. Ample arrangements were made for obtaining and circulating intelligence, and all lateral communications were improved and supplemented to the utmost. A light field-railway from Rémiilly to Pont à Mousson (14 m.) was also put in hand, but progress on this was very slow. The water-supply of the town was promptly interrupted, but the river water was quite drinkable.

Meanwhile, the French in Metz had been diligently at work. There was no real deficiency of ammunition and stores in the fortress, and provisions for forty days were reported in hand. Bazaine was still in communication with the outside world, though return messages came in sparingly. On the afternoon of the 25th he decided to break out to the northward by the right bank of the river, and orders to this effect were duly issued. Many delays arose in their execution, and it was not till 2 p.m. on the 26th that the troops were formed up ready for action. But at the last moment the marshals wavered. Calling a council of war on the heights of Fort St Julien, he asked the opinion of his subordinates, who were unanimously against the proposed sortie, principally because the artillery had only ammunition enough for a single battle! Besides, the Germans had long since become aware of the movement in progress, and all chance of surprise was past. It was also raining very heavily. Accordingly the sortie was abandoned.

On the 20th of August Bazaine received a despatch, dated the 27th, from MacMahon, according to which his army should have been at Stenay on the Meuse and farther to the south by the 30th. The marshals accordingly determined to renew the attempt of the 26th, and orders—almost a repetition of those of the previous occasion—were issued.

At this moment (Aug. 31) the positions of von Manteuffel's command (I. Corps and 3rd Landwehr division) were most dangerously extended, and a surprise at daybreak might have had far-reaching results. But the excessive hurry of being and band-play and the betrayal of the French design even before daybreak. Not until 3:30 p.m. was the concentration completed, and Bazaine again assembled his commanding officers to give them their final instructions. This time he adhered to his decision, and about 4 p.m. the attack opened (battle of Servigny or Noiselle); but his opportunity had been allowed to slip, and though his first onset overwhelmed the German outposts, their main line held good, and masses of guns unlimbering over a front of some 4 m. rendered all further attempts to break the German cordon abortive. Firing only ceased as darkness fell, and next morning the fighting was again renewed. But the whole French army was disheartened. It was obvious that what they had failed to do by surprise was hopeless now that twenty-four hours had been given in which the Germans could make counter-preparations. Therefore about noon a general retirement under the guns of the forts took place, and the last serious hope of the French army had vanished. Some 120,000 men with 538 guns had been engaged against 60,000 Germans with 222 guns, and had been beaten off with a loss of 3500 men. The Germans had lost about 3000.

The investment now resumed its regular course. The Germans, in the strength of their position on the left bank of the Moselle, drew more troops over to the right, and added to their defences and communications. The idea was even mooted of damming up the river near Haunoucourt, and thus flooding out the whole of the civil population of Metz; but expert civil engineers, who were sent for from Germany, reported against the proposal.

As time wore on the conditions in Metz and the surrounding camps became deplorable. The hospitals and private houses had been crowded with wounded from the first, and now, owing to the persistent wet weather, smallpox and dysentery became epidemic. Towards the close of September rations had to be reduced, and the troops began slaughtering the cavalry horses for food. Probably to cheer the men by a semblance of activity, Marshal Bazaine attempted a sortie on a large scale on the 1st of October in the direction of Ladorchamps, and fighting continued into the 2nd, but without prospect of success and the profound depression following on defeat sent up the spirit list rapidly. One other sortie towards Noiselle followed on the 7th, the alleged reason for which was the hope of obtaining provisions in the neighbouring villages. But it was beaten off with the utmost ease by the investing troops, who were well fed and cared for; and as by this time even the gun-teams had followed the cavalry horses to the slaughter-house, the French army as an army—but a combination of the three arms—had ceased to exist. On the recognition of this fact negotiations for the capitulation of Metz were begun on the 13th of October, and on the 14th the Army of the Rhine surrendered. Had it held out even forty-eight hours longer events before Paris and Orleans might have taken a different turn.

The investment of Metz had lasted 54 days, and the death-roll of the civil population had risen to 358; against 1200 in the corresponding period of a normal year. The army itself had only lost from sickness 2600 men, or barely 2% of its full effective.

(F. N. M.)

MEUDON, a town of northern France, in the department of Seine-et-Oise, 6 m. E. of Versailles by rail and about 23 m. S.W. of Paris. Pop. (1906), 9597. The remains of a castle (17th century) burned during the siege of Paris in 1871 have been adapted as an observatory. Its terrace commands a fine view of Paris. The handsome Government buildings, on the hill of Fleury, were founded by the duchess of Galliera for the reception of aged persons and orphans. The buildings were completed in 1885, at a cost of £560,000. The town has a monument of Rabelais, who was born there in 1553, and manufactures munitions of war for the artillery, and in the neighboring park of Chalais is the Government military ballooning establishment. In the 16th century the cardinal, Charles of Lorraine, built at Meudon a magnificent château, which was destroyed in 1863. The present remains belong to a building erected by the dauphin, son of Louis XIV. The wood of Meudon lies for the most part to the west of the town.

MEULEN, ANTONY FRANCIS VAN DER (1634-1690), Flemish painter, born in Brussels, was called to Paris about 1666 by Colbert, at the instance of Le Brun, to fill the post of battle painter to Louis XIV. His paintings during the campaigns of Fladgers (1667) so delighted Louis that from that date Van der Meulen was ordered to accompany him in all his expeditions. In 1673 he was received into the French Academy, attained the grade of councillor in 1681, and died full of honours in Paris in 1690. He is best represented by the series of twenty-three paintings, mostly executed for Louis XIV, now in the Louvre. The show that he always retained his Flemish predilections in point of colour, although his style was modified by that of the French school.
MEUNIER—MEUSE

MEURTHE-ET-MOSELLE, a department of north-eastern France, formed in 1871 out of those parts of the old departments of Meurthe and Moselle which continued French. Before 1790 it belonged to Lorraine, or to one or other of the bishoprics of Toul, Metz and Verdun. Pop. (1906), 517,508. Area 20,985 sq. m. It is bounded E. by Lorraine, N. by Belgium and the grand-duchy of Luxembourg, W. by the department of Meuse, and S. by that of Voges. Meurthe-et-Moselle is of a hilly character, the highest elevation, the Grand Rougigont (2041 ft.), being in the Voges. The valley of the Moselle runs through it from south to north. Extensive forests, the chief of which is the Forest of Haye, are found in the south-western region. Only a small part of the drainage of Meurthe-et-Moselle flows into the Meuse, by far the greater part reaching the Rhine by way of the Moselle. The principal affluents of the Moselle are the Madon and the Orné on the left, and on the right, besides the Meurthe, the Seille, which in one part of its course forms the boundary of Alsace-Lorraine. The principal tributary of the Meuse within the department is the Chiers. Climatically Meurthe-et-Moselle belongs to the Vogesan region, and has hot summers and severe winters. Its mean annual temperature is between 40° and 45° F., being 2° lower than that of Paris (which has the same latitude). The annual rainfall averages between 28 and 32 in. The department possesses much coal, and much iron; the chief crops are cereals and potatoes, together with clover, mangel-wurzels, tobacco, hops and beetroot. The vine is also cultivated, its best products being those of the Toul district. The most common fruit trees are the pear, the apple, the walnut, the cherry and the plum. Of forest trees the oak and the wych-elm are most frequent in the west of the department, the beech and the fir in the Voges. The French school of forestry has its seat at Nancy. The salt-workings (the chief of which lie between Nancy and St. Nicolas,) and the iron-mines (round Nancy and Longwy) of Meurthe-et-Moselle are the most productive in France. Other important industries are the manufacture of boots and shoes, straw and felt hats, pottery, and tanning and brewing (at Tontonville). Cotton and wool spinning, and the manufacture of cotton goods, hosiery, embroidery, chemicals (at Dombasle, close to Nancy), soap, tobacco, matches, crystal (at Baccarat, which has a population of 50,717, mirrors) glass, army clothing and paper may also be mentioned. The department is served by the Eastern railway, the chief line being that from Paris to Strassburg through Nancy. The main waterway is formed by the canal between the Marne and the Rhine. This canal communicates with the Meuse by means of a down-stream canal, through which it flows to the Meuse, and with the eastern canal which unites the Meuse and the Moselle with the Saône and the Rhone. The department constitutes the diocese of Nancy, has its court of appeal at Nancy, and forms a part of the district of the VI. army corps (Châlons-sur-Marne), and of the académie (educational division) of Nancy. There are 4 arrondissements (Nancy, Briey, Lunéville and Toul), 29 cantons and 588 communes. The principal towns of the department are Nancy, the capital, Lunéville, Toul, Longwy, Pont-à-Mousson and St. Nicolas. Other places of interest are Prény, with ruins of an important stronghold (21th and 13th centuries) of the dukes of Lorraine; and Vaudémont, seat of a famous countship, with ruins of a stronghold of the 12th and 14th centuries.

MEUSE (Flem. Maas, Du. Maas), a river rising at Pouilly, in the department of Haute Marne, France. After passing through a great part of Belgium and Holland it flows into the Waal channel of the Rhine at Fort Loevenstein. A few miles below Gorinchem the Meuse, or Waal as it is then called, divides into two branches. The northern flows almost due west, and joins the Lek (Rhine) above Rotterdam, and enters the North Sea at the Hook of Holland. Ocean. The eastern stream, however, the New Waerway (Nieuwe Waterweg), a little north of the Meuse. The southern branch turns south, crosses the marsh of Biesbosch by the canalized channel of New Merwede, enters the Hollandsch Diep, and reaches the sea by the arms called Haringvliet and Krammer.

Complete edition of his works by J. Lami (1781-1763). See Van der Aa's Biographisch Woordenboek der Nederlanden (1869), and J. E. Sands, Hist. of Class. Scholarship (1908), ii. 311.
The length of the Meuse is nearly 560 m., of which 360 are navigable, and probably its traffic is only exceeded by that of the Rhine. Near Bazelles it disappears under ground for a distance of over 3 m. The Chiers, the Semois, the Lesse, the Sambre, the Ourthe and the Roer are its most important tributaries. In Belgium it is canalized between Liège and Vise, and the Dutch are engaged on the same operation below Maestricht. The principal towns on the Meuse are: in France, Verdun, Séyan, Mézières and Givet; in Belgium, Dinant, Namur, Huy, Liège and Maastricht; in Holland, Maestricht, Roermond, Venlo, Dordrecht and Rotterdam.

MEUSE, a department of north-eastern France, formed out of a part of Lorraine (portions of the Three Bishoprics, and the Barrois and Clermontains) and Champagne. Pop. (1906), 280,220. Area, 2409 sq. m. It is bounded N. by Belgium and the department of Ardenne, E. by that of Meurthe-et-Moselle, S. by those of Vosges and Haute-Marne, and W. by those of Manne and Ardenne. About one-half belongs to the basin of the river Meuse, which is enclosed on the west by the wooded region of Argonne, on the east by the hills known as the Côtes de Meuse. On the north-east it is watered by the Orne, a tributary of the Moselle, and the Chiers, which runs from Montmédy to join the Meuse. The other, half sends its waters to the Seine by way of the Argonne. The river rises here, and by the Ornain, an affluent of the Saulx, the two last being tributary to the Marne. The highest elevation (1388 ft.) occurs to the south-west, on the line of the ridge which separates the basin of the Meuse from that of the Seine. The heights gradually sink from south to north, but seldom fall below 1000 ft. The hills of the Argonne similarly sink rapidly down to the valley of the Saulx, where the lowest level of the department (377 ft.) is reached. Its winters are less severe than those of the Vosges, but it is not so temperate as the Seine region. The average annual rainfall is about 30 in. The chief crops of the department are wheat, oats, rye, barley, clover, potatoes and mangel-wurzels. The vine is cultivated to some extent, the best growths being those of Bar. The forests, occupying more than a quarter of the area, are principally of oak, and are rich in game, as are the rivers in fish. Basket-making is prosecuted in the Argonne. The mineral wealth of the department includes good freestone (Euvre, Lérouville). It has iron and steel works, wire-works, and manufactories of files, hammers, and edge tools, and Ligny-en-Barrois (pop. 4879) manufactures scientific instruments. There are factories for wool-weaving, and hemp, flax and jute factories, sawmills, carriage works, leather manufactures, glassworks, paper-mills, distilleries and flour-mills. The department is served by the Eastern railway, the principal lines being that from Paris to Strassburg through Bar-le-Duc and Commercy, that from Paris to Metz through Verdun, and the branch line of the Meuse valley. The chief waterways are the canal connecting the Meuse with the Rhine and the Eastern canal along the Meuse valley; the two together have a length of 145 miles. Ecclesiastically the department forms the diocese of Verdun; it has its court of appeal at Nancy, and constitutes part of the district of the army corps of Châlons-sur-Marne, and of the educational division of Nancy. There are 4 arrondissements—Bar-le-Duc, Commercy, Montmédy and Verdun—28 cantons and 586 communes. The principal places in the department are Bar-le-Duc, the capital, Commercy, Verdun and St Mhiel, which receive separate treatment. Other places of interest are Avioth, which has a church of the 14th and 15th centuries with a 5th century spire, adjoined to it, and Remercourt-aux-Pots with a fine church of the 12th century.

MEUSE-LINE, the chain of French forts closing the passages of the Meuse between Verdun and Toul. The total length of the line is 31 m., and the forts d'arrêt are disposed along the right bank. The forts are: between Verdun and St Mhiel, Génicourt and Troyon; near St Mhiel, Les Paroches (left bank) and Camp des Romains; and near Commercy—Liouville St Aignan, Gironville and Jousy-sous-les-Côtes. Above the circle of the Toul defences there are barrier forts on the Upper Meuse at Pagny (la-Blanche-Côte) and near Neufchâteau; but these last are practically in second line, and between Toul and Épinal the frontier districts are designedly left open. At Épinal the "Mousseline" begins. These lines form part of the defensive scheme adopted by France in 1875-1875. Their general design is that of the French fort illustrated in Fortification and Siegecraft, fig. 43, though they are varied in accordance with the site.

MEVANIA (mod. Betagna), an ancient town of Umbria, on the river Clitumnus and on the Via Flaminia, 8 m. W.S.W. of Forum Flaminius, and 5 m. W. of Fulginius (Foligno), 738 ft. above sea-level. There are remains of a temple near the north gate, and of an amphitheatre built into the modern houses. The walls, which have disappeared, were, according to Pliny (Hist. Nat. xxxv. 173), built of unbaked bricks. In 310 B.C. the consul Fabius broke the Umbrian forces here; but otherwise it is not mentioned until the 1st century A.D. In 69 the army of Vitellius awaited here the advance of Vespasian. Its pastures near the river and its white oxen are mentioned by Propertius, whose family belonged to Assium (mod. Assisi) and after him by Silius Italicus, Lucan and Statius. The town was a municipium. The churches of S. Michele Arcangelo and S. Nicola are Romanesque buildings of the 12th century.

MEW, a chamber, an, a kind of let it be, a, term of art used in English practice, and also spelled miao, representing the cry of a cat or a sea-bird. The name mew, usually sea-mew, as applied to the Larus canus, or common sea-gull, is, according to Skeat, also imitative. As the name of the sea-bird it appears in Du. meeuw, Ger. Mwe, and other languages. (2) (Through Fr. muer, from Lat. mutare, to change), a term originally applied in French to the mounting of a hawk or falcon, and then to the caging of the bird during that period; thus "to mew up" has come to mean to confine. The English word chiefly survives in the plural form mews, applied to a stable-yard, coach-houses, stalls for horses, and living accommodation, found in narrow streets in large towns. This use was due to the Royal Mews at Charing Cross, where the royal hawks were kept from 1377 to 1537, when the building became the royal stables.

MEWS, PETER (1619-1706), English royalist and divine, was born at Caundle Purse in Dorset on the 25th of March 1619, and was educated at the Merchant Taylors' school, and at St John's College, Oxford, of which he was scholar and fellow. When the Civil War broke out in 1642 he joined the Royalist side and was soon made a captain, was taken prisoner at Naseby; but he was soon released, and in (1484) sought refuge in Holland. He became friendly with Charles I.'s secretary, Sir Edward Nicholas, and being skilful at disguising himself was very useful to the Royalists during the rule of Oliver Cromwell, undertaking two journeys to Scotland in 1653. Before this Mews had been ordained. Taking the degree of D.C.L. and regaining his fellowship at Oxford after the Restoration, he became archdeacon of Huntingdon, vicar of St Mary's, Reading, and chaplain to the king; then, having obtained two other livings, he was made canon of Windsor, canon of St David's, and archdeacon of Berkshire. In 1667, when at Breda arranging peace between England and Holland, he was chosen president of St John's College, Oxford, in succession to his father-in-law, Dr Richard Baily, afterwards becoming vice-chancellor of the university and dean of Rochester. Appointed bishop of Bath and Wells in 1672, Mews resigned his presidency in 1673, and in 1684 he was elected bishop of Winchester, a position which he held for the rest of his life, being on the 4th of November 1706. The bishop's palace is, built in Winchester, and it is said that he used it as a dockyard in war, and kept carriage horses to pull the cannon at a critical moment during the battle of Sedgemoor, where he was wounded whilst accompanying the royal army. He was, however, in sympathy with the seven bishops, and was only prevented from illness from attending their meeting; and as visitor of Magdalen College, Oxford, he supported the fellows in their resistance to James II., admitted their nominee, John Hough, to the presidency, and restored the ejected fellows in October 1688.
He took the oaths to William and Mary in 1680. In the absence of Compton, bishop of London, Mews took the chief part at the consecration of Dr Tholoton, archbishop of Canterbury in 1691. H. D. Rich, Life of William Morgan, 1876. See also G. C. I. Cassan, Lines of the Bishops of Winchester (1827); and the Nicholas Papers, edited by G. F. Warner (1886-1897).

MEXBOROUGH, an urban district in the West Riding of Yorkshire, England, on the Don, 11 m. N.E. of Sheffield on the Great Central and Midland railways. Pop. (1891), 7734; (1901), 10,430. The Don affords water communication with the Humber. The church of St John the Baptist has Early English portions. The large industrial population is mainly employed in glass, pottery and iron works, and in the neighbouring stone-quarries. The Castle Hill is crowned with some fine earthworks of uncertain date.

MEXICO (Span. Méjico, or Mexico), officially styled Estados Unidos Mexicanos and República Mexicana, a federal republic of North America extending from the United States of America southward to Guatemala and British Honduras, and lying between the Pacific Ocean on the west and the Gulf of Mexico and Caribbean Sea on the east. Its northern boundary line was fixed by the Guadalajara Mexican-American treaty of 1848. North of that treaty line is the Guatemalan republic, which the United States, Mexico, and Guatemala have all acknowledged. It follows the Rio Grande del Norte from its mouth north-westward to lat. 31° 47' N., thence on that parallel W. 900 m., thence S. to lat. 31° 20' N., thence due W. to the 11th meridian, thence in a straight line (nearly W.N.W.) to a point on the Colorado river 20 m. below the mouth of the Gila river, thence northward to the mouth of the Gila, and thence, nearly due W., along the old line between Upper and Lower California to a point on the Pacific coast one marine league S. of the southernmost point of San Diego Bay; this line has a total length of 1810 m., of which the Rio Grande comprises 1136 and the land route 674 m. The boundary line with Guatemala, for a long time in dispute, was fixed by the treaties of 1882 and 1895. It is an arbitrary line and follows only two natural lines of demarcation—the Suchiate river from the Pacific coast to its source, and the Chixoy and Usuamincas rivers from near the 16th parallel N.W. to a point on the latter 25 kilometres, S. of Tenoquite (Tabasco). Between these rivers the boundary line is determined by the peaks of Tacaná, Buenavista and Lzabal, and from the Usuamincas eastward it follows two parallels of latitude, one on the point of departure from that river, and the other, the longer, on that of 17° 49' to the British Honduras frontier. The boundary with British Honduras was determined by a treaty of 1863 and is formed in great part by the Hondo river down to the head of Chetumal Bay, and thence through that bay to the Boca Bacalar Chica—the channel separating Yucatán from Ambergis Cay. Geographically, Mexico extends from 14° 30' 42" (the mouth of the Suchiate) to 32° 42' N. lat., and from 86° 40' 08" to 177° 07' 31" W. long. Approximately its greatest length from N.W. to S.E. is 1900 m., its greatest width 750 m., and its least width a little short of 140 m. In outline it is sometimes compared to a huge cornucopia with its small end curving S.E. and N. The interior curve formed by the Gulf of Mexico is comparatively regular and has a coast-line of about 1400 m. The Caribbean coast-line is about 527 m. long, exclusive of islands. In the western coast of Mexico this line, which is relatively deep, is deeply broken by the Gulf of California, and has a coastline of 4574 m., including that of the Gulf. The peninsula of Lower California (q.v.) lies parallel with the mainland coast and extends southward to about 24° 52' N.lat., a distance of nearly 760 m. The area of Mexico is commonly given by English authorities as 767,005 sq. m., by German statisticians as 1,087,501 sq. km. (767,200 sq. m.), and by H. H. Bancroft, who quotes official figures, as 1,962,899 sq. km. (757,997 sq. m.).

Physiography.—The surface features consist of an immense elevated plateau with a chain of mountains on its eastern and western margins, which extends from the United States frontier southward to the Isthmus of Tehuantepec; a fringe of lowlands (tierras calientes) between the plateau and coast on either side; a detached, roughly mountainous section in the south-east, which belongs to the Central American plateau, and a low sandy plain covering the greater part of the Isthmus of Yucatán. The peninsula of Lower California is traversed from north to south by a chain of barren mountains which covers the greater part of its surface. The slopes are precipitous on the east coast, but on the west they are less abrupt and more gently undulating. The slope is probably considered a southward continuation of the Californian Sierra Nevada. The great plateau of Mexico is very largely of volcanic origin. Its superstructure consists of igneous rocks of all descriptions; in many places these rocks have been filled by volcanic action. The remains of transverse and other ranges are to be seen in the isolated ridges and peaks which rise above the level of the table-land, in some cases forming isolated volcanic cones; but well marked mountain ranges are several thousand feet in height above the plateau and have a more regular character and level. The two noteworthy depressions in its surface, the Valley of Mexico and Bolsón de Mapimí, once contained large bodies of water, of which only small lakes and marshy lagoons now remain. The highest part of this great plateau is to be found near the city of Mexico and the plateau of the eastern part of the basin of Mexico is about 8000 ft. Southward the slope is broken into small basins and terraces by transverse ranges, and is comparatively abrupt. Northward the slope is gentle, and is broken by several transverse basins or river valleys in the eastern part of the basin of Mexico. The low land to the north of the eastern frontier, the elevation is 3600 ft., which shows a slope of only 43 ft. to the mile. Less is definitely known of the elevations of Chiapas, on the border of Guatemala, which are separated from the main system by the Gulf of May and the line of divides, the Sierra Tarahumara and Sierra del Durango, and the most western as the Sierra del Nazareno, Sierra Yaqui and Sierra Fuerte. These chains converge in southern Sinaloa and Durango to form the Sierra de Nayarit. Near the 20th parallel the great chain again divides, the eastern chain consisting of the Sierra de Jalisco, a small range between the western, or Sierra Madre del Sur, following the shore line closely to Tehuantepec. The Sierra Madre Occidental has but few noteworthy elevations, its culmination points being the Nevado de Toluca (17,888 ft., highest peak), which is in the state of Mexico, and the El Cerro del Peral (17,419 ft.), which is in the state of Jalisco. In the Sierra de Nayarit the Cerro Pinal rises to an elevation of 11,319 ft., and in the extreme south the Cerro de la Llengue to 10,502 ft. These sierras lying near the coast have an imposing appearance from the sea, and their general elevation is so dwarfed as to render them comparatively inconspicuous. The Sierra Madre Oriental consists of a broken chain of ranges extending along the eastern margin of the Mexican plateau, the greatest part of which is about 5000 ft. above the sea-level, the elevation about the 20th parallel. In the north these ranges are low and offer no great impediment to railroad building. South of Tampico, however, they are concentrated in a single lofty range. This range (Arabat Mts.) rises to between 6000 and 7000 ft. (peak of Del terra Cruz (state) and includes the snow-capped cone of Izalco or Iztaltepetl (18,209 ft.), and the Cerro de Peorote, or Nanchampactel (15,419 ft.). The eastern slopes are abrupt and difficult, and are a serious impediment to the communication between the Mexican plateau and the open plateau half way between this region and the city of Mexico is the isolated cone of Malinché, or Malintzin (14,636 ft.). Crossing the highest part of the Mexican Plateau is a broken series of ranges, forming the water-basin by which the northern part of the state of Mexico is drained. These ranges return eastward on the 20th parallel and cross the plateau in a south by east direction. Southward the plateau is traversed by many low ranges and breaks down in terraces, forming one of the most fertile and attractive parts of the Republic. All along the line the Sierra Madre Occidental has a height of point is 13,078 ft. above sea-level, the Nevado de Toluca (15,168 ft.), in a range which separates the valleys of Mexico and Toluca, the Montes de las Cruces, and that volcanic, spur-like range, running northward at the south of the other range to which they converge, some 20 m. south-east of the city, are the gigantic, snow-clad volcanoes of Popocatepetl (Smoking Mountain) and Ixtaccihuatl (White Woman). Both of them are extinct and Popocatepetl has been in action recently. The naval expeditions Geographe Exploradora, 17,888 and 17,343 ft. respectively, of Ixtaccihuatul being the highest of its three crests. This part of Mexico is highly volcanic in character, the transverse ridges described having a large number of extinct volcanoes and at least three (Colima, Jorullo and Ceboruco) that are either active or semi-active. Colima was in a state of eruption as late as 1999.
Jorullo (4262 ft.) is said to date from 1750, when its cone was formed, and Ceboruco (7100 ft.) in the territory of Tepic, shows occasional signs of activity. Near the coast in the state of Vera Cruz is San Martin, or Tuxtlas (9708 ft.), which has been quiescent since its violent eruption on the 29th of March 1793. Orizaba is sometimes included among the semi-active volcanoes, but this is a mistake. It has been quiescent since 1566, and is now completely extinct. Earthquakes are common throughout the greater part of the republic, especially on the western coast. They are most violent from San Blas southward to the Guatemala frontier, and some of the Spanish towns on or near this coast have suffered severely. Chichipango, in Guerrero, was badly shattered in 1902, and in 1907, and in 1909 was reduced to a mass of ruins. The earthquake shocks of the 39th and 31st of July, 1909 were unusually severe throughout southern Mexico, reducing Acapulco and Chichipango to ruins and shaking the city of Mexico severely. In Acapulco a tidal wave followed the shock. Slight shocks, or temblores, are of almost daily occurrence. According to Humboldt's theory there is a deep rent in the earth's crust about the 19th parallel through which at different periods the underground fires have broken at various points between the Gulf of Mexico and the Revillagigedo Islands. "Only on the supposition that these volcanoes, which are on the surface connected by a skeleton of volcanic rocks, are also united under the surface by a chain of volcanic elements in continual activity, may we account for the earthquakes which in the direction mentioned cause the American continent, from the Gulf of Mexico to the Pacific Ocean, to oscillate at the same time." (Egloffstein, p. 37).

The lowland or tierra caliente region, which lies between the sierras and coast on both sides of Mexico, consists of a sandy zone of varying width along the shore-line, which is practically a tidal-water plain broken by inland channels and lagoons, and a higher belt of land lying to an elevation of about 3000 ft. and formed in great part by the detritus of the neighbouring mountain slopes. On the Pacific side there are places where the mountain spurs extend down to the coast, but in general this lowland region ranges from 10 to 40 miles wide, except in southern Vera Cruz, Tabasco, Campeche and Yucatan, where it extends farther into the interior. The talus zone of this region, especially at elevations of 1000 to 3000 ft., is noted for its great fertility and the luxuriance of its vegetation.

There are no large islands on the coast of Mexico, and most of the smaller ones are unimportant. Many of those that fringe the Gulf coast are sand-keys, or parts of a new coast formation. They are commonly barren and uninhabitable. The Isla del Carmen, which partly shuts in the Laguna de Terminos (Campeche), is one of the largest of this class, and has the town and port of Carmen at its western extremity. On the northern coast of Yucatan is the small, inhabited island of Holbox or Holboy, and on the eastern coast the islands of Mujeres, Cancun and Cozumel, of which the first and last have a considerable population and good ports. On the Pacific coast there are a number of islands off the rocky shores of Lower California and in the Gulf of California—most of them barren and uninhabitable like the adjacent coast. The largest of these, some of them inhabited, are Guadalupe—about 75 m. west of the coast on the 29th parallel, which is fertile and stocked with cattle; Cerros, off Viscaino Bay, and Santa Margarita, which partly shelters Magdalena Bay, on the Pacific side; and Angel de la Guarda, Tiburon, San Marcos, Carmen, Monserrat, Santa Catalina, Santa Cruz, San Jose, Espiritu Santo and Cerralvo in the Gulf. Lying off San Blas in the broad entrance to the Gulf are the Tres Marias, and directly west of Colima, to which it belongs, is the scattered volcanic group of Revillagigedo.

The peculiar surface formation of Mexico—a high plateau shut in by mountain barriers, and a narrow lowland region between it and the coast—does not permit the development of large river basins. Add to this the light rainfall on the plateau and a lack of forests, and we have conditions which make large rivers impossible. The hydrography of Mexico, therefore, is of the simplest description—a number of small streams flowing from the plateau over mountain slopes eastward to the Gulf of Mexico and westward to the Pacific. Most of these are little more than mountain torrents, but one has a course exceeding 500 m., and have navigable channels. The principal watered river is formed by the streams of the state of Mexico, from which streams flow north-east to the Gulf of Mexico, north-west to the Pacific and south-west to the same coast below its great eastern curve. The Rio Grande del Norte, or Rio Bravo, on the northern frontier is practically an American river. It rises in American territory and receives very little water from the Mexican side. Its larger Mexican tributaries are the Rio de los Conchos, Salado and Pesqueria. Of the Suchiate and Hondo, which form part of Mexico's southern boundary, the first is a short, impetuous mountain torrent flowing into the Pacific, and the other a sluggish lowland stream rising in north-eastern Guatemala and flowing north-east through a heavily forested region to Chetumal Bay. The peninsula of Yucatan has no rivers, and that of Lower California only a few insignificant streams in the north. This is due to the porosity of the soil in the former, and the very limited rainfall in the latter. The largest rivers of Mexico are: the Rio Grande de Santiago, called the Lerma above Lake Chapala, rising in the state of Mexico and flowing westward across Guanajuato, Jalisco and
The Pacific coast, with a total length of 540 m., is bordered by the Gulf of California, which is bordered by the Sierra Madre Occidental. The Guadalupe and the Sierra Madre by the Gulf of California, with a length of 390 m.; the Grijalva, which rises in the mountains and flows north-west across Tabasco to the Gulf of Mexico; and the Tuxpan, which has its source in the north-west of the state of Mexico and flows north-eastward to the Gulf of Mexico. The rivers are long, slow, and have a large surface flow, but many on the Gulf coast are navigable for considerable distances. The more important of these are in Tabasco—the Grijalva, navigable for about 63 m., and the Usumacinta, for about 270 m. The country along the Laguna de Términos is low and flat, and is traversed in all directions by deep, sluggish streams. The rivers crossing the lowlands bordering the Gulf have short navigable channels, the most important of which is the Pánico. This river is navigable for small vessels up to Matamoros (31 m.), and for smaller craft 65 m. farther. Nearly all the Gulf coast rivers, however, are obstructed by bars owing to the quantity of silt brought down from the sierras and the prevailing winds and currents on the coast.

The course of the Gulf of California is still more restricted than that of the Gulf of Mexico. It has no lateral bays or estuaries, and is separated by the broad archipelago of the islands of the Gulf of Tehuantepec and California. The former is opposite the Gulf of Campeche, and possesses no distinguishing characteristic. The Gulf of California, on the other hand, penetrates the continent for a distance of 739 m., from south-east to north-west, with a maximum breadth of 190 m. Its area is usually restricted to the waters north of the latitude of Punta San Lucas, but it should be extended to the outer waters enclosed by a line from Cape San Lucas to Cape Corrientes. Its upper waters are not much navigated because of the aridity of its coasts, but there are two or three important ports towards the south. The Gulf has a considerable number of islands, most of them a few hundred miles from the coast. These are divided into two groups—those of the La Paz and Santa Iñes in Lower California, Guaymas in Sonora, Agiobampo, Topolobampo, and Altalana in Sinaloa. On the Pacific coast of Lower California, are the Ensenada de Guadalupe, Ensenada de Trinidad, and Ensenada de San Cristobal. The principal bays on the mainland coast are Olas Atlas, which is the harbour of Mazatlán, San Blas, Banderas, Manzanillo, Acapulco, Salina Cruz and Tonalá. Several of these are being improved.

There is a continuous series of river estuaries, some of which are navigable only at particular periods, from the Mexican border to the mouth of the Los Angeles River, about 260 m. long. They are formed largely by the wash of the Pacific, and are occupied by sediments of Cretaceous and later date, the pre-Cretaceous rocks occurring only in comparatively small and isolated patches. At the southern extremity of the great table-land, however, in the state of Puebla, there are extensive deposits of the Lower Cretaceous series, which must be of Archaean age. Similar rocks occur also in Chiapas, Oaxaca, Guerrero and elsewhere; but owing to the absence of any early fossiliferous deposits, the age of these rocks is very uncertain. The great estuary of the Magdalena, which penetrates for several miles into the heart of the mountains, is one of the few localities, but for the present the observations are open to doubt. The earliest fossiliferous beds which have been proved to exist in Mexico belong to the Carboniferous system. They are found on the west coast of the Isthmus of Tehuantepec, and in chili, and consist of limestones and dolomites with Productus oyster beds.

The Mesozoic beds are of greater importance. The Triassic and Jurassic systems are met with only in scattered patches. The Triassic consists of sandstones and clays, and the fossils found in them are of little importance. The Jurassic is represented by the Cretaceous beds are divided, but the Cretaceous is divided into two characteristic genera of the Indian Gondwana system. The Jurassic beds are marls, sandstones and limestones, which contain marine fossils. The Cretaceous rocks take a far larger share in the formation of the country. They form the greatest part of the Sierra Madre Oriental and also cover most of the central plateau. They contain many fossils, including Hippurites and Ammonites. The sedimentary deposits of the Tertiary era do not occupy a very wide area. They occur, however, along the coast, where they are marine, and also on the central plateau, where they are of lacustrine origin. But by far the most important of the Tertiary rocks are the volcanic lavas, agglomerates and ashes, which occupy a very large area on the coast, in the states of Tabasco and Chiapas. They are of the greatest importance, for they are the most developed, and give rise to the southern extremity of the plateau which they spread nearly to the eastern coast. The eruptions are said to have begun with the ejection of syenites, which are still found in the Mexican Gulf, and were followed by a series of basaltic eruptions, which have continued to the present day.

Climate.—Mexico stretches across 17 parallels of latitude, with the Tropic of Cancer crossing her territory about midway. This implies tropical and sub-tropical conditions. The relief of the land and the existence of the mountains modify these conditions in many important particulars. The elevation and extent of the great central plateau, which penetrates westward from Vera Cruz, and the presence of parallel mountains, give rise to a marked difference between the Gulf and Pacific coastlines of Mexico in regard to their minor indentations and harbours. The coast has no bays of importance, its rivers are obstructed by sandbars, and it has only one natural harbour—that of Campeche and the Laguna de Términos (Campechay), but no distinction is necessary. This coast has no bays of importance, its rivers are obstructed by sandbars, and it has only one natural harbour—that of Cármen and the Laguna de Términos (Campechay), but no distinction is necessary. deeply into the tropical half of the country, carry with them temperate and sub-tropical conditions over much the greater part of the republic. Above the plateau rise the marginal sierras, while a few isolated peaks in the region of perpetual snow give to Mexico a considerable area of cold temperate and a trace of arctic conditions. Descending to the lowlands on either side of the plateau, the temperature rises steadily until the upper limit of the tropical region, called tierras calientes, is reached, where the climate is hot, humid and unhealthy, as elsewhere in the forested coastal plains of tropical America.

The tierras calientes (hot lands) of Mexico include the two coastal zones, the Isthmus of Tehuantepec, the states of Tabasco, Campeche, and part of Chiapas, the peninsula of Yucatán and a part of eastern Oaxaca. In temperature these areas are considereably depressed from the northern plains; the temperature rises steadily until the upper limit of the tropical region, where the climate is hot, humid and unhealthy, as elsewhere in the forested coastal plains of tropical America.

Flora and Fauna. —The types of animal and vegetable life found in Mexico belong, in a general sense, to those of the northern temperate region, and those of the tropical regions of Central and South America. The great central plateau and its bordering lowlands form an intermediate territory in which these dissimilar types are found side by side, the tropical species extending northward along the coast toward the Gulf of California, and the temperate types found their way to the southern limits of the plateau. The jaguar and puma have found their way into the United States, while the wolf, coyote, bear and beaver have gone far southward on the plateau, and the buffalo was once found in large numbers on its fertile northern plains. Man, however, does not apply to south-eastern Mexico, where animal life is represented by many of the genera and species found in the forested lowlands of the great Amazon basin. Four regions of the fauna of Mexico include at least five species of monkey, the jaguar, puma, ocelot (Felis pardalis), wolf, coyote, lynx, badger, otter (Lutra felina), beaver, muskrat, bear, racoon (Procyon), coyote, and the black-billed cuckoo, from which are derived the name of the country.

The Mexican species of the arboreal porcupine (Spheneutes mexicanus), the kinkajou (Cercopithecus auriculatus), three species of deer—the white-tailed Cervus tuleus, the little black-billed brocket, Coassus rufus, which is also found in Brazil, and the Sonora deer (Odocoileus cervus)—the Mexican bighorn (Ovis mexicana), and the Mexican agouti (Dasyprocta lataattus), marten, several species of opossum (including a pigmy species of the Tres Marias islands), sloth, two species of ant-bear (Myrmecophaga tetradactyla and Cyclobothus didactyla), armadillo (Dasypod nigricans), and the kinkajou (Cercopithecus auriculatus), three species of deer—the white-tailed Cervus tuleus, the little black-billed brocket, Coassus rufus, which is also found in Brazil, and the Sonora deer (Odocoileus cervus)—the Mexican bighorn (Ovis mexicana), and the Mexican agouti (Dasyprocta lataattus), marten, several species of opossum (including a pigmy species of the Tres Marias islands), sloth, two species of ant-bear (Myrmecophaga tetradactyla and Cyclobothus didactyla), armadillo (Dasypod nigricans), and the kinkajou (Cercopithecus auriculatus). by the Aztec rulers for their own exclusive use. Of the indigenous birds, the turkey has been fully domesticated, and the musk-duck and "chachalaca" are easily reared. Sea-fowl are most numerous on the coasts of Lower California, where certain species of the arid belt of Tehuantepec, but they are not generally distributed. It should be noted that some of the migrating birds of North America pass the winter in Mexico.

The insect fauna of Mexico covers a vast range of genera and species, and the most remarkable feature is the great number of species found in the tropics. The butterflies, beetles, ants, and the myriads of mosquitoes, midges, flies, and chinchons. Among the mosquitoes, which are extraordinarily numerous in some of the hot lowland districts, are the black-spotted "sugarcane" and white "sugarfly.

The midges are even more numerous than the mosquitoes. In pleasing contrast to such pests are the butterflies of all sizes and colours, beetles of an inconceivable variety of shape, and the whole of the animal kingdom of the tropics. The insects of the warmest regions are the least numerous, and the most remarkable of those found there are the butterflies, beetles, ants, and the myriads of mosquitoes, midges, flies, and chinchons. Among the mosquitoes, which are extraordinarily numerous in some of the hot lowland districts, are the black-spotted "sugarcane" and white "sugarfly.

var. elongata which produces the “henequen” fibre, or sisal hemp, of Yucatán, silk or tree-cotton (Celosia cassaria), sugar-cane, cotton (Gossypium), indigo and “canagire” (Ramex hymenosepalus) whose root contains a large percentage of tannin.

Mexico has suffered much from the reckless destruction of her forests, not only for industrial purposes but through the careless burning of grassy areas. The denuded mountain slopes and plateaus of southern Mexico are due to the prehistoric inhabitants who cleared away the natural forest for their Indian corn fields, and then left them to the erosive action of the tropical rains and subsequent occupation by coarse grasses. Fire was generally used in clearing these lands, with the result that their arboral vegetation was ultimately killed and their fertility destroyed. In the valley of some of these denuded slopes oak and pine are succeeding the tropical species where fires have given them a chance to get a good foothold.

Population.—According to the census of 1900 the population of Mexico numbered 13,607,759, of which less than one-fifth (19%) were classed as whites, 38% as Indians, and 43% as mixed bloods. There were 57,507 foreign residents, including a few Chinese and Filipinos. Since then the Japanese have acquired an industrial footing in Mexico. Under the constitution of 1824 all race distinctions are abolished, and these diverse ethnic elements are nominally free and equal. For many years the races in Mexico have intermarried and taken no part in the political activities of their native country. Since about 1866, spurred on by the consciousness that one of their own race, Benito Juárez, had risen to the highest positions in the gift of the country, they have taken greater interest in public affairs and are already making their influence felt. In southern Mexico the Zapotecus furnish schoolmasters for the village schools. Peonage, however, is still prevalent on many of the larger estates, and serious cruelties are sometimes reported.

The government itself must be held partly responsible, as for the transportation of the mountain-bred Yaquis to the low, tropical plains of Yucatán (see Herman Whitaker’s The Planter, 1909), but the influence of three and a half centuries of slavery and peonage cannot be shaken off in a generation.

According to Humboldt, the census of 1810 gave a total population of 6,122,334, of which the whites had 18%, the mestizos 22% and the Indians 60%. The census of 1895 increased the whites to 22%, which was apparently an error, the mixed bloods to 47%, and reduced the Indians to 31%. It is probable that the Indians were, with regard to the mixed bloods and Indians, but it is the general conclusion that the Indians have been decreasing in number, while the mixed bloods have been increasing. Neglect of their children, unsanitary habits and surroundings, tribal intermarriage and peonage are the principal causes of the decreasing Indian population.

Recent observers, however, deny the assertion that the Indians are now decreasing in number except where local conditions are exceptionally unfavourable. The death rate among their children is estimated at an average of not less than 50%, which in families of five or six children, on an average, permits only a very small natural increase. The larger part of the population is to be found in the southern half of the republic, owing to the arid conditions prevailing in the north. The unhealthfulness of the coastal plains prevents their being thickly populated, although Vera Cruz and some other states return a large population. The most favourable regions are those of the tierras templadas, especially on the southern slopes of the northern central plateau which were thickly populated in prehistoric times.

The dissimilar races that compose the population of Mexico have not been sufficiently fused to give a representative type, which, it may be assumed, will ultimately be that of the mestizos. Mexico was conquered by a small body of Spanish adventurers, whose success in despoiling the natives attracted thither a large number of their own people. The discovery of rich deposits of gold and silver, together with the coveted commercial products of the country, created an urgent demand for labourers and led to the enslavement of the natives. To protect these adventurers and to secure for itself the largest possible share in these new sources of wealth, the Spanish crown forbade the admission of foreigners into these colonies, and then harassed them with commercial and industrial restrictions, burdened them with taxes, stranded them with monopolies, and even refused to permit the free emigration thither of Spaniards.

Out of such adverse conditions has developed the present population of Mexico. It was not till after the middle of the 19th century that a long and desperate resistance to foreign intervention under the leadership of Benito Juárez infused new life into the masses and initiated the creation of a new nationality. Then came the long, firm rule of Porfirio Diaz, who first broke up the organizations of bandits that infested the country, and then sought to raise Mexico from the state of discredit and disorganization into which it had fallen. Suspicions and jealousy of the foreigner is disappearing, and habits of industry are displacing the indolence and lawlessness that were once universally prevalent.

The white race is of Spanish descent and has the characteristics common to other Spanish-American creoles. Their political record previous to the presidency of Porfirio Diaz was one of incessant revolutionary strife, in which the idle, unsettled half-breeds took no unwilling part. The Indian element in the population is made up of several distinct races—Aztec, Mixtec-Zapoteca, Maya or Yucatecan, Otomi or Othomi, and in smaller number the Totonac, Tarasco, Apache, Matlanzingo, Chontal, Mixe, Zoque, Guaiacuro, Opatapina, Tapijulapa, Seri and Huave. As the tendency among separated tribes of the same race is to develop dialects and as habitat and customs tend still further to differentiate them, it may be that some of these smaller families are branches of the others. In 1864 Don Manuel Orozco y Berra found no fewer than 31 distinct languages and 69 dialects among the Indian inhabitants of Mexico, to which he added 62 extinct idioms—making a total of 182 idioms, each representing a distinct tribe. Thirty-five of these languages, with 69 dialects, he succeeded in classifying under 11 linguistic families. A later investigator, Don Francisco Belmar (Lenguas indígenas de Mexico, Mexico, 1909), has been able to reduce these numerous idioms to a very few groups. None of them were written except through the use of ideographs, in the making of which the Aztecs used colours with much skill, while the Mayas used an abbreviated form, or symbols.

The Aztecs, who called themselves Mejica or Mexicans after they had established themselves on the high table-land of Mexico, belong to a very large family or group of tribes speaking a common idiom called Nahua or Nahoa. These Nahua-speaking tribes were called the Nahuatlaca, and compose a little more than one-fourth of the present Indian population. They inhabit the western Sierra Madre region from Sinaloa southward to Chiapas, the higher plateau states, which region was the centre of their empire when Cortés conquered them, and parts of Vera Cruz, Tabasco, Oaxaca, Morelos, Aguascalientes and San Luis Potosi. They were energetic and warlike and evidently had not reached the zenith of their power when Cortés came. They had been preceded on the same plateau by the Chicimecs, possibly of the same race, who were conquered by the Aztecs sometime in the 13th century after a supposed occupation of the territory about 400 years. The characteristic civilization of prehistoric Mexico, however, antedates both of these periods.

An Aboriginal race called the Toltecs is said to have occupied Vera Cruz and Tabasco and to have extended its empire westward on the plateau to and perhaps beyond the present capital. They were the builders of the pyramids of Cholula and Teotihuacan, near the city of Mexico, and of Papantla, Huatusco and Tuzapan, in Vera Cruz. One of their towns was Tollan (now Tula) 30 m. north of the national capital, and it is not improbable that the people of Cholula, Texcoco and Tlaxcala at the time of the Spanish invasion were occupying the sites of older Toltec towns. There has been much discussion in regard to the origin of the Toltecs, some assuming that they were a distinct race, and others that they belonged to the Nahuatlaca. Another and perhaps a better supposition is that they belonged to the Maya group, and represented a much earlier civilization than that of the builders of Palenque, Quirigua and Copan. Confirmatory
in weaving baskets, hangings, mats, screens and various household utensils. Copper was known to them, and it is possible that they knew how to make cutting instruments from it, but they generally used stone axes, hammers and picks, and their most dangerous weapon was a war-club into which chips of volcanic glass were set. Many of these primitive arts are still to be found in the streets, and perhaps the best work in pottery moulding in Mexico today is that of uneducated Indian artists.

Of the half-reed element which has become so important a part of the Mexican population, no safe estimate can be made. Education, industrial occupation, commercial training and political responsibility are apparently working a transformation in a class that was once known chiefly for indolence and criminal instincts, and many of the leaders of modern Mexico have sprung from this race. Settled government, settled habits, remunerative employment and opportunities for the improvement of their condition are developing in them the virtues of the two parent races. Dignity was formerly so common that travel without an armed escort was extremely dangerous; under President Diaz, however, not only has such lawlessness been repressed but the brigands themselves have been given regular employment as rural guards under the government. This class is also furnishing the small traders of the towns, overseers on the plantations and public works, petty officials, and to some extent the teachers and professional men of the provincial towns.

**Political Divisions.**—The republic of Mexico is politically divided into 27 states, one federal district, and three territories. The states are generally subdivided into *distritos* (districts) or *partidos*, and into municipalities (municipios) which correspond to the townships of the American system. The state of Nuevo Leon, however, is divided into *municipios* only, while some other states use entirely different titles for the divisions, the larger being described as *departamentos*, *cantones* or *municipios*, and the smaller as *partidos*, *directorios* and *vecindarios*; the Federal District consists of thirteen municipalities. The territory of Lower California is divided into two large districts, northern and southern, and the latter into *partidos* and *municipios*—the larger divisions practically forming two distinct territories.

The states and territories, with their areas, capitals and populations, are as follows:

The area and population of Yucatán include those of the territory of Quintana Roo, which formed part of that state at the time of the census.

Baja, or Lower California, is divided into three districts for administrative purposes: Baja California, Baja California Sur, and the District of Guaymas. The only town of any importance is Mexicali, with a population of 7,583 and has its capital at Ensenada (pop. 10,262); the District of the South has a population of 40,041 and has its capital at La Paz.

The Gulf coast is about 1,000 miles in extent, and its area was broken by the Republic of Texas and by the United States. Mexico had some of its earliest settlements on the Gulf coast. The Gulf coast is divided by the State of Tamaulipas. It is the center of the Mexican manufacturing, textile, and iron industries. It is also the center of the nation's commerce, which is carried on with foreign countries.

The Gulf of California, or the Sea of Cortez, is the southernmost extension of the Pacific Ocean. It is about 500 miles in width and has a number of islands, including Guadalupe, Isla de la Juventud, and Isla del Carmen. The Gulf of California is an important trade route for the United States.

cotton, woolen and linen textiles and yarns for national factories, hardware, furniture, building material, mining supplies, drugs and chemicals, wines and spirits, wheat, Indian corn, paper and military supplies and equipment. The exports include gold, silver, copper, coal, bituminous coal, sisal, jute and other fibres, cabinet woods, chicle, rubber and other forest products, hides and skins, chickpeas, tobacco and sugar.

Agriculture.—The agricultural resources of Mexico are large and utilize on the part of the population. A great variety of food products of the temperate zone, and most of the leading products of the tropics. Agriculture, however, received slight attention, owing to the early development of the mining industries. An increased interest in the industrial development of Mexico, which began during the last part of the 19th century, has been accompanied by increased interest in agriculture, and especially in undertakings requiring large investments of capital, such as coffee, sugar and rubber plantations. A large part of the country is too arid for agriculture, and even where the rainfall is sufficient, staple food with the poorer classes, the deficiency is made up through importation. These drawbacks tend to restrict agriculture on the plateau to comparatively limited areas, and the country people are, in the main, engaged in the cultivation and husbandry of the trees that new product in this region is that of canaigue, which is grown for the tannin found in its root. It is a native of the arid regions and is now cultivated with success. The district about Parras, in southern Coahuila, is well known for its almond, for which distinct origin is the facture of wine and brandy. An important product of the plateau and of the open districts of the tierras calientes, growing in the most arid places, is the "nopal" or prickly pear cactus (Opuntia ficus indica), chirimoya (Annona diversifolia), sapote (Sapota diploptera), the several "zapote" fruits, including "chico zapote" from the Aracacia sapota, which produces the "chila" or "chicle-gum of commerce, "zapote blanco" from the Carissa spinulosa, "zapote- blanco" from the Carissa spinulosa, "zapote gris" from the Diospyros ocellata, and "zapote-mamey." The production of rubber is becoming an important industry, large plantations having been set up with both Hevea and Coicosa rubber trees. The large rubber trees are grown on the dry subtropical belt where coffee of an excellent quality is produced, and where cotton is cultivated. Coffee has become an important export, but cotton does not yield enough for the domestic market and is grown on a smaller scale because the market is limited. The pulque, which is produced from the sap of the agave, is fermented and made into an alcoholic beverage. The mescal is made from the agave, and is used in the production of many liquors called "pulque" and "mescal." In Yucatan immense plantations of the Agave rigida var. elongata are cultivated, from which large quantities of "henequin" or "sisa," as the fibre is called, is obtained and produced for export. The Mexican American finds favourable conditions for its growth—a dry calcareous surface with moisture sufficiently near to be reached by its roots. Its cultivation is the chief industry of the states of Mexico, Hidalgo, Puebla and Tlaxcala. Of the plantation states of the east, Coahuila were devoted to the production of this fibre. The plant is propagated from suckers and requires very little attention after transplanting to the field where it is to remain, but it takes six to eight years to mature and then yields an average of ten gallons of sap. The pulque, "pulque" is the distilled spirit made from the leaves and roots of the plant. There are other agaves used both in the production of drinks and fibres, but they are not cultivated. The fibre of the agave, from Tampico and Chiapas is all obtained from the agaves and yuccas found growing wild.

The natural and forest products of Mexico include the agave and yucca (sily) fibres already mentioned; the "ceibon" fibre derived from the silk-cotton tree (Bombax pentandria); rubber and vanilla in addition to the cultivated products; palm oil; castor beans; guayule, the source of latex for the rubber tree (Ficaria sapota); logwood and other dye-woods; mahogany, rosewood, ebony, cedar and other valuable woods; "casacote" or divi-divi; jalap root (Ipomoea); saraparilla (Smilax); nuts and fruits, including dates and figs.

Stock-raising dates from the earliest Spanish settlements in Mexico and received no slight encouragement from the mother country. For this reason much importance has always been attached to the industry. The grassland is of such a nature as to be found in every state of the country, though not always to a great extent. The Spaniards found no indigenous domestic animals in the country, and introduced their own horses, cattle, sheep and swine. From these are descended the herds of flocks of to-day, with no admixture of foreign blood. The horses and cattle are of a degenerate type, small, unguainly and incur to neglect and hard usage. The horse is chiefly used for saddle purposes and is not reared in large numbers. The mule is much more intelligent and better adapted for service as a draft and pack animal. The transport of merchandise and produce was wholly by means of pack animals before the advent of railways, and is still the common means of transport away from the railway lines. For this purpose the sure-footed mule is invaluable. In some districts, however, oxen and ox-carts are employed, especially in the southern states, and always in the open, level country. The varying climate and varying conditions of the pastures have not only departed from the original Spanish type, but likewise present strikingly different characteristics among themselves. Those of the northern plateau are small, hardy and long-lived, being adapted to the low and humid climate of the lowlands and to the feeding on native grasses and weeds; whereas the southern plateau is more temperate, and the pasturage is better grasses, in which case the horses are imported, and the animals are generally rated among the best in Mexico. Withstanding the severity of winters and the frequent droughts, cattle-raising is a precluded industry among the lowlands of the southwest, and especially near the American frontier. Almost total losses are frequently experienced, but the profits of a favourable year are so great that losses seldom deter ranchers from trying again. In the areas where conditions are suitable, cattle-raising is a precluded industry among the lowlands of the southwest, and especially near the American frontier. Almost total losses are frequently experienced, but the profits of a favourable year are so great that losses seldom deter ranchers from trying again. In the areas where conditions are suitable, cattle-raising is a precluded industry among the lowlands of the southwest, and especially near the American frontier.
to a large number of the natives in the province, and the considerable quantity of the shell and other products are exported. Other industries of a descriptive character include the production of archil, or Spanish moss, on the western side of the California peninsula, hunting herons for their plumes and aligators for their skins, honey extraction, and the gathering of corral and piñon insects. The cochineal insect was once an important commercial product, but the industry has fallen into disrepair. The "ni"-"in" (also known as "axi") is a small scale insect belonging to the genus Coela, found in Yucatán. It is distinguished from the New World varieties by the small size of the worker, where it inhabits the spongia trees and produces a greasy substance called "nina," which is much used by the natives as a varnish, especially for domestic utensils, as it resists fire as well as water.

The most productive productive industry of Mexico is that of mining. It was the chief object of Spanish exploration, and the principal occupation of European residents and capital during three centuries of Spanish rule. Agricultural and pastoral industries gradually grew in importance, but they were always of great importance, but mining continued far in advance until near the end of the 19th century. Mines of some description are to be found in 29 of the 31 states and territories, and of these the great majority yield silver. According to the official reports were registered in September 1900, 21,911 mining properties, of which nearly five-sixths were described as producing silver, either by itself or in combination with other metals. The properties were classified as: 1,772 gold, 3,585 silver, 970 copper, 385 iron, 35 mercury, 95 lead, 43 bismuth, 17 zinc, 7 copper, 7 bismuth, 2 mercury, 2 zincon, 1 iron, 1 lead, 1 bismuth, 1 mercury, and 1 zincon. The remaining are various combinations of these metals. The absence of coal from this list is due to the circumstance that coal mining has not been developed to any extent, and is not registered under the general mining laws. A comparison with 1888-1889, when 8,790 properties were registered, will show how rapidly the mining industry has been developed during that period. Besides those in the table above, the following also exist: asphalt, platinum, graphite, soda, and marble. In 1906 the productive mines numbered 1,268, of which 491 were in Sonora, 282 in Chihuahua, 271 in Durango, 171 in Oaxaca and 105 in Nuevo León. Gold is found in Durango, Chihuahua, and Oaxaca; silver, in San Luis Potosí, Zacatecas, and to a limited extent in other states; iron, in every state and territory except Campeche, Chiapas, Tabasco, Oaxaca, Puebla, Sinaloa, Sonora, Vera Cruz, and Zacatecas; coal is found in San Luis Potosí, Guanajuato, Durango, Hidalgo, Oaxaca, and other states; and lead in Hidalgo, Querétaro, and in many of the silver-producing districts. The most celebrated iron deposit is that of the Cerro del Angel, in the state of Durango, and the town of San Antonio, which is known as "Cerro del Angel." It is located on a mountain 640 ft. in height, 700 ft. in breadth, and 4800 ft. in length, and is reputed to be a solid mass of iron. Large masses of the metal are also found said to exist in the sierras of Lower California. The principal coalfield is that of Sonora, and the town of Saltillo is the centre of the industry. They have been opened up by American capitalists and the coal is used on the railways passing through that region. Mexican coal is of a low grade—similar to that found in Texas, but as an official geological report of 1908 estimates the annual output of this brown or impure sugar to the country cannot be considered inferior to that of the precious metals. The same is true of the petroleum deposits in Tamaulipas, near Tampico, and in the southern Vera Cruz. An investigation by the U.S. Geological Survey in 1905 showed that the Mexican Petroleum was of good quality, but that while not as rich as those found in the upper Mississippi basin for refining purposes, they furnish an excellent fuel for railway engines and other industrial purposes. Many of the Mexican railways are operated by American firms which are making headway. In 1909 a well was opened in the southern oilfields whose yield was larger. The product being largely consumed in the rural districts and never appearing in the larger markets. The estimated number of sugar mills was 1300, of which only about 300 were important for size and equipment. Merino sheep were introduced in 1847 and woolen factories manufacture from that date. Large woolen factories are now to be found in all parts of Mexico, and good and serviceable grades of broadcloth, cassimere, blankets and other fabrics are turned out. There is also a considerable quantity of carpeting, underlayment, and other articles of woven fabrics. An important branch of the industry is the manufacture of "zarapes" (called "ponchos" in other parts of Spain and America)—a blanket slung in the centre for the head to pass through, and worn in place of a coat by men of the lower classes. The most important textile industry is that of matting. The manufacture of matting is an important feature in the industrial life of the republic. There were 140 factories in 1906, of which 19 were large, and these were distributed over a very large part of the country. About one-half the raw cotton consumed and cotton products manufactured in the country, the consumption of its various products being large among all classes of the population. There were 467 tobacco factories reported in 1906 to be engaged in the manufacture of cigars, cheroots, cigarettes, snuff, and cut tobacco for the pipe. The number of factories reported for 1890 was 743, but as the consumption of leaf tobacco increased from 5,546,677 to 8,587,564 kilogrammes, it may be assumed that the decrease in factories is due to the absorption or discontinuance of the more unimportant methods of manufacture. Some other important manufactures are flour mills, of which there were over 100 in 1904; iron and steel works, of which there are 7 large establishments, including the immense plant at Monterey; 1906, and many smaller establishments; sugar factories, in which sugar is made from sugar cane, and factories for the manufacture of hats, paper, linen, hosiery, harness and saddles, matches, explosives, aerated waters, soap, furniture, chocolate, and sweets. There are also a large number of distilleries, breweries, and establishments for the manufacture of "panama" hats and imitation or counterfeit methods. Other important manufactures are flour mills, of which there were over 100 in 1904; iron and steel works, of which there are 7 large establishments, including the immense plant at Monterey; 1906, and many smaller establishments; sugar factories, in which sugar is made from sugar cane, and factories for the manufacture of hats, paper, linen, hosiery, harness and saddles, matches, explosives, aerated waters, soap, furniture, chocolate, and sweets. There are also a large number of distilleries, breweries, and establishments for the manufacture of "panama" hats and imitation or counterfeit methods. Other important manufactures are flour mills, of which there were over 100 in 1904; iron and steel works, of which there are 7 large establishments, including the immense plant at Monterey; 1906, and many smaller establishments; sugar factories, in which sugar is made from sugar cane, and factories for the manufacture of hats, paper, linen, hosiery, harness and saddles, matches, explosives, aerated waters, soap, furniture, chocolate, and sweets. There are also a large number of distilleries, breweries, and establishments for the manufacture of "panama" hats and imitation or counterfeit methods. The policy of the Mexican government is to encourage manufactures and to make the necessary laws for that purpose. Other favours are given in taxation and exemption from import duties on machinery and raw materials. These inducements have attracted large sums of foreign capital and the industry is said to be more solid and skillful than that of the operatives, especially in the cotton and wool and smelting industries.

Constitution.—Under the Constitution of the 5th of February 1857, subsequently modified in many important particulars, the government of Mexico is described as a federation of free and sovereign states invested with representative and democratic institutions. Practically it is a Federal Republic with centralized executive powers. Its political divisions consist of 27 states (originally 19) having independent local governments, 3 territories and 1 federal district in which the national capital stands. The central government consists of three co-ordinate branches—executive, legislative and judicial—each nominally independent of the other. The executive branch consists of a president and vice-president, assisted by a cabinet of 8 secretaries of state: (1) foreign affairs; (2) interior; (3) justice; (4) public instruction and fine arts; (5) fomento, colonization and industry; (6) communications and public works; (7) finance and public credit; (8) war and marine. The president and vice-president are elected indirectly through an electoral college chosen by popular vote, and serve for a period of six years (the term was four years until 1904), the vice-president succeeding to the office in the event of the death or disability of the president. The office of vice-president was created on the 6th of May, 1904, and that official serves as president of the senate. A constitutional amendment of 1890 permits the re-election of the president without limit, the original clause prohibiting such a re-election. A candidate for the presidency must be a native-born Mexican
citizen in the full exercise of his political rights, 35 years of age, not an ecclesiastic, and a resident of the republic at the time of the election. Although the authority of the president is carefully defined and limited by the Constitution, the exercise of dictatorial powers has been so common that the executive may be considered practically supreme and irresponsible. Previous to the presidency of General Porfirio Diaz in 1877 political disorders and changes in government were frequent.

The legislative branch of government consists of a Congress of two chambers—a senate and a chamber of deputies. Two ordinary congressional sessions are held each year—April 1 to May 31 and September 16 to December 15—and a permanent committee of 29 members (14 senators and 15 deputies) sits during recess, with the power to confirm executive appointments, to give assent to a mobilization of the national guard, to convene extra legislative sessions, to administer oaths, and to report at the next session on matters requiring congressional action. The senate is composed of 56 members—or two from each state and from the federal district—who are elected by popular vote for a term of four years, one-half the number retiring every two years. A senator must be not under 30 years of age, Mexican citizen in the full enjoyment of his rights, a resident of the state he represents, and not an ecclesiastic.

The chamber of deputies is composed of popular representatives, in the proportion of one deputy for each 40,000 inhabitants or fraction over 20,000, who are elected for a term of two years. A deputy must be not less than 25 years of age, other qualifications being the same as those for a senator. The salary for either senator or deputy is $5000 and that of the president $50,000.

Federal officials and ecclesiastics are ineligible for election to either chamber.

Mexican citizens include all persons born of Mexican parents, all naturalized aliens, and all foreigners owning real estate in the republic or having children by Mexican mothers unless formal declaration is made of an intention to retain the citizenship of another country. As in some cases exceptions are granted from specified taxes and military duties, others are not, native-born and naturalized citizens are treated the same as native-born. Aliens are granted the civil rights enjoyed by Mexicans, but the government reserves the right to expel those guilty of pernicious conduct. Suffrage is extended to all Mexican citizens who possess honest means of livelihood, the age limit being 18 for the married and 21 for the unmarried.

The judicial branch of the government consists of a supreme court of justice, three circuit courts, and 32 district courts. The supreme court is composed of 11 "ministros" or justices, four alternates, a "fiscal" or public prosecutor and the attorney-general—all elected by popular vote for a term of six years. It has jurisdiction in cases arising from the enforcement of the federal laws, except cases involving private interests, in admiralty cases, in cases where the republic is a party, in those between two or more states, or between a state and the citizens of a foreign state, in those originating in the federal district, and in those affecting diplomatic and consular officials. There are likewise superior and inferior courts in most of the states, governed by the civil and criminal codes in force in the federal district. The territories are governed by federal laws. The department of justice has oversight in matters relating to the enforcement of the federal laws and the administration of justice through minor courts. The police service is both municipal and federal in character. In some states a local police service is maintained, but in most states the federal government maintains a very efficient force of mounted "rurales."

The states are organized very much like the federal government, each with its own governor, legislature, laws and judiciary. Elections are generally indirect, like those for the national executive, and official terms correspond closely to those of similar offices in the national organization. The state is nominally divided into its own boundaries, and the authority of its officers and courts in local questions is supreme except in cases where federal intervention or supervision is provided for by the federal constitution. The larger political divisions of the state (partidos, distritos, &c.) are governed by a jefe político, or prefect, and the smaller by a municipal council called an ayuntamiento.

Defence—The Mexican army consists of 24,132 officers and 24,132 men, organized on modern lines, and commanded by a general staff at the capital. There were 30 battalions of infantry and 4 battalions cadres with an effective strength of 730 officers and 7300 men; 14 regiments and 6 cavalry regiments with 493 officers and 6058 men; 2 regiments and 3 cadres of field artillery; one regiment and one cadre each of horse and mountain artillery, 4 sections of garrison artillery, and one mitrailleur and machine gun company. The personnel of the army is divided among other services. Administration and headquarters staffs comprised 885 officers and 531 men. This force represented the peace footing of the army, which is recruited in part by voluntary enlistments and in part by selection that might be called impression. Mauser rifles (1901 model) and rifles and carbines are used by the infantry and cavalry, and Schneider Canet quick-firing guns by the field and horse artillery. The nominal war strength is rated at 16,504, but the reserve and reserve reserves, 9,954 men. Factories for arms and ammunition have been established within the territory, and uniforms and other equipment are made in the country. The military school in the capital occupies a part of the historic castle of the Popocatépetl, and is now thoroughly reorganized on modern lines. There is also an artillery school at Vera Cruz, and subdelegado schools in other parts of the republic. The national guard, to which reference is sometimes made, has no effective organization.

Mexico may be said to have no navy, the ten small vessels in commission in 1908 had a complement of not more than 40 officers and 300 men, with two old dispatch boats and 2 old unarmoured gunboats, a steel training cruiser, the "Zaragoza," and 5 small modern gunboats. The personnel consisted of 198 officers and 905 men. Six new cruisers were ordered in 1898, but the remnants of the old navy were kept in reserve as military schools are maintained at Campeche and Mazatlán.

Education.—Education in Mexico may be said to have entered upon a progressive phase. The institutions founded by the Spaniards were wholly under ecclesiastical control. Following independence, Mexico was founded during the administration of Vicerey Mendoza (1835-1850), but it taught very little beyond Latin, rhetoric, grammar and theology. The university of Mexico, planned by Mendoza and founded on the 21st of September 1553, with faculties of law, philosophy and theology. Practically nothing was done for the natives beyond oral instruction in the catechism. The university of Mexico received an important impulse from the law of January 1555, which gained a position comparable to the universities of South America, Córdoba, Lima (San Marcos) and Bogotá. The overthrow of Spanish rule in Mexico was the beginning of a new period, and efforts were made to produce educational reforms, but the colonial upstart ecclesiastics were still governed by their fears and prejudices and little was accomplished. In 1583 the university of Mexico suspended work, and in 1656 passed out of existence altogether. In 1857 the adoption of a more liberal and democratic constitution passed the way for a new period in the educational history of the country. Education was delayed by the wars that devastated the country down to the overthrow of Maximilian, but the leaven was at work, and the return of the republic in 1867 in the number of primary and secondary schools was noted. Colleges of medicine and engineering were created in Mexico City in 1865 in place of the old university and were successful from the beginning. In 1876, schools did not come into effect until after the enactment of the law of 1896. This law provided for elementary public education, and compulsory attendance for children of 6 to 12 years of age. Preparatory courses for professional training in the government schools were also made free and secular. As the
states have control of the schools within their own boundaries there was at first a great lack of uniformity, but the national system is being generally adopted. In the official report for 1904 the number of public schools, exclusive of infant schools, was returned at 579,495 against 491,750 in 1899. Of these 488,625 were supported by the national and state governments and 276 by the municipalities. The private, religious and association schools numbered 2,281, with 135,838 pupils. For secondary instruction the national and state schools numbered 36 with 4,842 pupils. The school age is 6-15, and there were in May 1905, 37,900 women. Normal schools for the training of teachers are also maintained at public expense and are giving good results. Besides these, the government maintains schools of law, medicine, agronomy, veterinary practice, engineering, mechanics, agriculture, and administration, music and fine arts. There is also a mechanics' training school (arte y oficio) for men and a similar school for women, schools for the blind and for deaf-mutes, reform schools, and boys' schools. Early, estimates have been made that 90% of the population were illiterate. In 1895 this percentage was reduced to about 84%, and the work of the schools is slowly cutting it down. Mention must be made of the National Library in Mexico City, with about 225,000 volumes, and 138 public libraries (in 1903), in other parts of the republic, 34 museums for scientific, educational and art purposes, and 11 meteorological observatories. Newspapers and periodicals, whose educational value varies widely, numbered 426 in 1904, of which 439 were in Spanish and 12 in English.

Religion.—The predominant religion is Roman Catholicism, the census of 1900 returning 13,533,013 communicants of that church, 51,795 Protestants (in great part foreigners), 2,811 of other faiths, and 18,640 of no faith. The constitution of 1857 grants toleration to other creeds, and the Roman Catholic church has the same privileges as other churches, and has established mission stations in the towns, but their numbers are still comparatively small. The Roman Catholic religion was enforced at the time of the conquest, but a large percentage of the native population is now professedly semi-pagan, and the people are divided into various grades of religious sensibility. The number of the faithful being worshipped in secret, and the forms and tenets of the dominant faith, which they faintly comprehend, being largely adulterated with superstitions and practices of pagan origin. The church of Mexico was divided into 9 archbishoprics and 52 bishops. It dates from the creation of the bishopric of Mexico in 1533, with Fray Juan de Zumarraga as bishop, although two previous creations had been proclaimed at Rome, that of Yucatan in 1519 and Puebla in 1539. The bishops of Mexico are the heads of an archdiocese, and are included in the Roman Catholic Church, and was finally suppressed on the 31st of May 1820. The great power exercised by the Roman Catholic Church during the colonial period enabled it not only to mould the spiritual life of the people, but to control in considerable measure the industrial and commercial life, and to determine the political policies governing their daily life. In this way it acquired great wealth, becoming the owner of extensive property in every part of the country and of highly productive properties in the towns and villages. The church owned 5,983,315 acres in 1888, amounting to about one-third of the real and personal property of the republic. The reform laws of that year nationalized its property, abolished its numerous orders and institutions and deprived it of state support and of all participation in the state's fiscal administration. Subsequent legislation removed clerical influence from public instruction, made marriage a civil ceremony and closed all conventual establishments. The church still exercises a boundless influence over the Mexican lower classes, and is still the most influential organization in the republic.

Finance.—The national revenues are derived from import and export duties, port dues and other taxes levied on foreign commerce; from excise and stamp taxes and other charges upon international business transactions; from direct taxes levied in the federal district and national territories, covering a land tax in rural districts, a local tax in the city, commercial and professional licences, water rates, and sundry taxes on bread, pulpoe, vehicles, saloons, theatres, &c.; from probate duties and registry fees; from a surcharge on all taxes levied by the federal government, a surcharge on the national debt paid in federal revenue stamps; from post and telegraph receipts, and from some minor sources of income. The most fruitful revenue is the duty on imports, which is sometimes used for the protection of national industries, but which in 1905 was increased to 4% on all foreign and domestic goods. The other principal sources of revenue are the export of raw silver and gold, 21% on partially refined ores, and 13% on pure silver. The expenditures are chiefly for the services of the public debt, military expenses, public works and internal affairs (Department of the Interior). The public debt service alone required $26,201,873 ($2,620,187) in 1898.

For the fiscal year 1906-1907 the revenue produced a total of 114,866,122 pesos (dollars), or, approximately, £11,428,612, and the expenditure was 85,076,643 pesos, or £8,507,643. The estimates for 1908-1909 show a marked decline owing to the commercial depression, the revenue being computed at 103,358,000 pesos, and the expenditure at 103,205,830 pesos. Of the former 46,500,000 pesos are credited to import duties, 31,930,000 pesos to stamps, excise taxes, &c., 10,930,000 pesos to direct taxes, and the balance to interest on the debt. In the circumstances that the greatest majority of the Mexican people own no property, carry no industry, and are not even to be considered regular productive labourers, the revenues are small in relation to the population and are contributed without any voluntary exertion on the part of the people, except that small proportion which is raised for charitable purposes.

The revenues and expenditures of the states and municipalities in 1904, the latest date available, aggregated as follows:

<table>

</tr>
</tbody>
</table>

The taxes cover a great variety of occupations and property, often to a minute and vexatious degree, and the expenditure includes the expenses of local administration, schools, police, streets and other objects of purely local interest.

The public indebtedness of Mexico includes a foreign debt payable in gold, an internal debt payable in silver, and a floating debt covering unpaid balances on appropriations, unpaid interest, and other credits and obligations. The paper money issues are by banks and not by the government, and the national treasury keeps no cash in its hands and has no sinking funds to offset its liabilities. The foreign debt dates from 1825, when $16,000,000 were borrowed in London through two loans. Interest defaults led to a conversion of the debt in 1851, the interest rate being reduced from 5% to 3%, while the outstanding amount was increased by the issue of 6% gold-bonding. From this time, the Mexican government has met its obligations promptly, in consequence of which its credit is rated high and its bonds have even been quoted at a premium. In 1896, the government placed a loan of $22,700,000 in London at 5% for the conversion of its 6% bonds, being it by the hypothecation of 6% of its import and export duties. Further loans have considerably increased the debt since then. In 1906-1907, the government repaid a loan of $12,000,000 to the British government on the security of its local resources. This is the only Mexican government that has met its obligations promptly, as the railways and public works were also included. The rate of interest is at 3%, 5%, and both principal and interest are payable in silver.

The rapid development of railway construction has largely increased this part of the public debt, the revenues of the country being insufficient to meet the sub-odd obligations, but as the railways are built for the development of valuable resources and the opening of needed trade communications, the increase has occasioned no loss of credit. At the end of 1908 the total public indebtedness of the republic was:

Previous to 1905 all monetary transactions in Mexico were based in practice on the gold standard and free coinage. By a law of the 9th of December 1904, a monetary system by an executive decree of the 25th of March 1905, the gold standard was adopted, and the silver peso, 902 fine and containing 24-438 grammes of pure silver, was made the monetary unit with a valuation of 75 grammes of gold. At the same time the free coinage of silver was suspended, the government reserving to itself the sole privilege of coining money. The coinage of Mexico, now concentrated at the mint in the capital (all others having been closed, was based, since November 28, 1907), on the decimal system—the peso being divided into 100 centavos—and consists of gold, silver, nickel and bronze coins, whose weight and fineness are determined by the monetary law of 1904. The coins minted under this law are:

The first called a "hidalgo" and the second a "medio hidalgo".
MEXICO

Hans Marie Santiago

I. Ancient Mexico.

The name Mexico is connected with the name of the group of American tribes calling themselves Mexico (sing. Mexicai) or Azteca. The word is related to or derived from the name of the Mexican national war-god, Mexitl, better known as Huitzilopochtli. The Aztecs from the 12th century appear to have migrated from place to place over the mountain-walled plateau of Anahuac, the country "by the water," so called from its salt lagoons, which is now known as the Valley of Mexico. About 1325 they founded on the lake of Texcoco the permanent settlement of Mexico Tenochtitlan, which is still represented by the capital city, Mexico. The name México was given by the conquerors to the group of countries over which the Aztec power more or less prevailed at the time of the European invasion. Clavigero (Storia antica del Messico, vol. i.) gives a map of the so-called "Mexican empire," which may be roughly described as reaching from the present Zacatecas to beyond Guatemala; it is noticeable that both these names are of Mexican origin, derived respectively from words for "straw" and "wood." Eventually Mexico and New Mexico came to designate the still vaster region of Spanish North America, which (till cut down by changes which have limited the modern republic of Mexico) reached as far as the Isthmus of Panama on the south and took in California and Texas on the north. Mexico in this wide sense is of high interest to the anthropologist from the several native American civilizations which appear within its limits, and which conveniently if loosely group themselves round two centres, the Mexican proper and the Central American.

When early in the 16th century the Spaniards found their way from the West India Islands to this part of the mainland of America, they discovered not rude and simple tribes like the islanders of the Antilles, but nations with armes, official administrators, courts of justice, high agriculture and mechanical arts, and, what struck the white men especially, stone buildings with fine sculpture and a sense of form and detailed elaboration to astonish the builders and sculptors of Europe. Here was a problem which excited the liveliest curiosity and gave rise to a whole literature. Hernando de Acosta shared the opinion of their time that the great fossil bones found in Mexico were remains of giants, and that, as before the deluge there were giants on the earth, therefore Mexico was peopled from the Old World in antediluvian times. On the other hand the multitude of native American languages suggested that the migration to America took place after the building of the tower of Babel, and Siguenza arrived at the curiously result that the Mexicans were descended from Naphtuhim, son of Mizraim and grandson of Noah, who left Egypt for Mexico shortly after the confusion of tongues. Although such speculations have fallen out of date, they induced the collection of native traditions and invaluable records of races, languages and customs, which otherwise would have been lost for ever. Even in the 19th century Lord Kensington spent a fortune in printing a magnificent compilation of Mexican picture-writings and documents in his Antigüedades de México to prove the theory advocated by Garcia a century earlier, that the Mexicans were the lost tribes of Israel. Modern archaeologists approach the question from a different point of view but the origin of the American aborigines and of Mexican civilization remains extremely obscure (see AMERICA, where the primitive Mexican cultures are fully illustrated, and CENTRAL AMERICA).

Real information as to the nations of Mexico before Spanish

1In this, as in all other Aztec names, the x (or j) represents the English sound sh; hence Mexitli and Mexhico should be properly pronounced Meshitli, Meshicho. But they do not appear to have ever been so pronounced by the Spaniards, who naturally gave to the x its ordinary Spanish sound of the German ck.

Important works of reference are: Anuario estadístico de la República Mexicana (Mexico); Mexican Year-book (London, 1898); Biologia y demás publicaciones of the U.S. Department of

SILVER: 1 peso, .927 fine, containing 24.436 grammes of pure silver, 50 centavos, .800 fine, 20 centavos, .400 fine, 10 centavos, .200 fine.

NICKEL: 5 Nickel, .800 nickel, .200 nickel.

BRONZE: 1 and 2 centavos, 93 parts copper, .4 tin, 1 zinc.

Provisions are also made for continuing the coinage of "trade dollars" for export, which have a wide circulation in the Orient but are not current at home. Fractional silver coin is not legal tender, and bronze and nickel clout have been portrayed of coins but the government maintains conversion offices where such coins can be converted into silver pesos without loss. The amount of gold in circulation is small, the bank notes convertible into gold taking its place. Foreign coins are permitted to circulate in the republic.

There were 34 chartered banks in Mexico in 1908, of which 29 enjoyed the privilege of issuing bank notes; the total note circulation on the 31st of December 1906 was 97,787,878 pesos. These note issues are everywhere current at full nominal value, being secured under the provisions of the national banking law of 1896 by metallic reserves. The notes are not legal tender, and it is forbidden to count them as "cash on hand" in bank returns, but ample safeguards have been adopted to check and reduce the risk to correspondents in their employment as a substitute for gold. Restrictions on speculative operations in real estate and on the use of hypothecated and discounted paper as security for other transactions, together with the publication of detailed monthly balance sheets, have kept these banks free from unsound methods, and their record thus far (1906) has been conspicuously good. Mortgage and loan banks have also been established in accordance with the law of 1896, and are subject to official supervision. Private banks are numerous, but foreign banks are not extended to open agencies. The use of cheques is very limited because of the stamp tax.

Weights and Measures.—Mexico adopted the metric system in 1862, and it is used in all official transactions, land measurements, railways, public works and public sales. The weights and measures, modified in many particulars, continued in private use, however, and in 1895 it became necessary to declare the metric system the only legal system and to make its use compulsory as of September 15 of that year.

BIBLIOGRAPHY.—The historical student will find valuable material in Bernal Diaz del Castillo, Crónica de la conquista de Nueva España (Madrid, 1632, and other dates); Antonio Herrera Historia general de los hechos de los Castellanos en las islas y tierra firme del mar occíncio (4 vols., Madrid, 1679); H. C. MacNutt, Letters of Corts to Charles V. (London, 1908); W. H. Prescott, Conquest of Mexico (3 vols., London, 1845); and the works of Gomara, Helps, Kingsborough, Las Casas, Sahagun and Justin Winsor.

Among the recent works on Mexico are Baedeker's The United States, with Excursions to Mexico, &c. (Leipzig, 1899); H. H. Bancroft, Resources and Development of Mexico (San Francisco, 1893); M. Chevalier, Le Mexique ancien et moderne (Paris, 1886); A. G. Calvo, Las ruinas de las ciudades americanas (Mexico, 1886); A. G. Seler, Antiquités de l'Amérique Centrale, Part 2 (Stuttgart, 1886); V. times is very imperfect, but not altogether wanting. The accurate and experienced Alexander von Humboldt considered the native Americans of both continents to be substantially similar in race-characters. Such a generalization will become sounder, if, as is now generally done by anthropologists, the Eskimo with their pyramidal skulls, dull complexions and flat noses are removed into a division by themselves. Apart from these polar nomads, the American indigenes group roughly into a single division of mankind, of course with local variations. If our attention is turned to the natives of Mexico especially, the unity of type will be found particularly close. The native population of the plateau of Mexico, mainly Aztecs, may still be seen by thousands without any trace of mixture of European blood. Their stature is estimated to be about 5 ft. 3 in., but they are of muscular and sturdy build. Measurements of their skulls show them mesocephalic (index about 78), or intermediate between the dolichocephalic and brachycephalic types of mankind. The face is oval, with low forehead, high cheek-bones, long eyes sloping outward towards the temples, fleshy lips, nose wide and in some cases flat but in others aquiline, coarsely moulded features, with a stolid and gloomy expression. Thickness of skin, masking the muscles, has been thought the cause of Japanese heaviness in the outline of body and face; the complex varies from yellow-brown to chocolate (about 40 to 43 in the anthropological scale); eyes black; straight coarse glossy black hair; beard and moustache scanty. Among variations from this type may be mentioned higher stature in some districts, and lighter complexion in Tehuantepec and elsewhere. If now the native Americans be compared with the races of the regions across the oceans to their east and west, it will be seen that their unlikeness is extreme to the races eastward of them, whether white Europeans or black Africans. On the other hand they are considerably like the Mongolid peoples of north and east Asia (less so to the Polynesians); so that the general tendency among anthropologists has been to admit a common origin, however remote, between the tribes of Tartary and of America. This original connexion, if it may be accepted, would seem to belong to a long-past period, to judge from the failure of all attempts to discover an affinity between the languages of America and Asia. At whatever date the Americans began to people America, they must have had time to import or develop the language of these families of languages actually found there, in none of which has community of origin been satisfactorily proved with any other language-group at home or abroad. In Mexico itself the languages of the Nahua nations, of which the Aztec is the best-known dialect, show no connexion of origin with the language of the Otomi tribes, nor of these with the languages of the regions of the ruined cities of Central America, the Quiche of Guatemala and the Maya of Yucatan. The remarkable phenomenon of nations so similar in bodily make but so distinct in language can hardly be met except by supposing a long period to have elapsed since the country was first inhabited by the ancestors of peoples whose language has since passed into so different forms. The original peopling of America might then well date from the time when there was continuous land between it and Asia.

It would not follow, however, that between these remote ages and the time of Columbus no fresh immigrants have reached America. We may put out of the question the Scandinavian sea-rovers who sailed to Greenland about the 10th century. But at all times communication has been open from east Asia, and even the South Sea Islands, to the west coast of America. The importance of this is evident when we consider that late in the 10th century Japanese junks still drifted over by the ocean current to California at the rate of about one a year, often with some of the crew still alive. Further north, the Aleutian islands offer a line of easy sea passage, while in north-east Asia, near Bering's Strait, live Chukchi tribes who carry on intercourse with the American side. Moreover there are details of Mexican civilization which are most easily accounted for on the supposition that they were borrowed from Asia. They do not seem ancient enough to have to do with a remote Asiatic origin of the nations of America, but rather to be results of comparatively modern intercourse between Asia and America. Humboldt (Vues des Cordilleres, Pl. xxiii,) compared the Mexican calendar with that in use in eastern Asia. The Mongols, Tibetans, Chinese and other neighbouring nations have a cycle or series of twelve animals, viz. rat, bull, tiger, hare, dragon, serpent, horse, goat, ape, cock, dog, pig, which may possibly be an imitation of the ordinary Babylonian-Greek zodiac familiar to ourselves. The Mongolian peoples not only count their lunar months by these signs, but they reckon the successive days by them, rat-day, bull-day, tiger-day, &c. and, also, by combining the twelve signs in rotation with the elements, they obtain a means of marking each year in the sixty-year cycle, as the wood-rat year, the fire-tiger year, &c. This method is highly artificial, and the reappearance of its principle in the Mexican and Central American calendar is suggestive of importation from Asia. Humboldt also discussed the Mexican doctrine of four ages of the world belonging to water, earth, air and fire, and ending respectively by deluge, earthquake, tempest and conflagration. The resemblance of this to some versions of the Hindu doctrine of the four ages or yuga is hardly to be accounted for except on the hypothesis that the Mexican theology contains ideas learnt from Asiatics. Among Asiatic tribes to which attention has since been called is the Mexican belief in the nine stages of heaven and hell, an idea which nothing in nature would suggest directly to a barbaric people, but which corresponds to the idea of successive heavens and hells among Brahmans and Buddhists, who apparently learnt it (in common with our own ancestors) from the Babylonian-Greek astronomical theory of successive stages or concentric planetary spheres belonging to the planets, &c. The Spanish chronicles also give accounts of a Mexican game called patolli, played at the time of the conquest with coloured stones moved on the squares of a cross-shaped figure, according to the throws of beans marked on one side; the descriptions of this rather complicated game correspond closely with the Hindu backgammon called pachisi (see Tylor in Jour. Anthropol. Inst., viii. 110).

The native history of Mexico and Central America is entitled to more respect than the mere recollections of savage tribes. The Mexican pictures so far approached writing proper as to set down descriptions of persons and places and the course of events, and at least helped the professional historian to remember the traditions repeated orally from generation to generation. Thus actual documents of native Aztec history, or copies of them, are still open to the study of scholars, while after the conquest interpretations of these were drawn up in writing by Spanish-educated Mexicans, and histories founded on them with the aid of traditional memory were written by Ixtilxochitl and Tezozosomoc. In Central America the rows of complex hieroglyphs to be seen sculptured on the ruined temples probably served a similar purpose. The documents written by natives in later times thus more or less represent real records of the past, but the task of separating myth from history is of the utmost difficulty. Among the most curious documents of early America is the Popol-Vuh or national book of the Quiche kingdom of Guatemala, a compilation of traditions written down by native scribes, found and translated by Father Ximenes about 1500, and published by Scherer (Vienna, 1857) and Brassee de Bourbourg (Paris, 1861). This book begins with the time when there was only the heaven with its boundaries towards the four winds, but as yet there was no body, nothing that clung to anything else, nothing that balanced itself or rubbed together or made a sound; there was nought but the calm sea alone in the silent darkness. Alone were the Creator, the Former, the Ruler, the Feathered Serpent, they who give being and whose name is Gucumatz. Then follows the creation, when the creators said "Earth," and the earth was formed like a cloud or a fog, and the mountains appeared like lobsters from the water, cypress and pine covered the hills and valleys, and their forests were peopled with beasts and birds, but these could not speak the name of their creators, but could only chatter and croak. So man was made first of clay, but he was strengthless and senseless.
and melted in the water; then they made a race of wooden mummies, but these were useless creatures without heart or mind, and they were destroyed by a great flood and pitch poured down on them from heaven, those who were left of them being turned into the apes still to be seen in the woods. After this comes the creation of the four men and their wives who are the ancestors of the Quichés, and the tradition records the migrations of the nation to Túlan, otherwise called the Seven Caves, and thence across the sea, whose waters were divided for their passage. It is worth while to mention these few early incidents of the national legend of Guatemala, because their Biblical incidents show how native tradition incorporated matter learnt from the white men. Moreover, this Central American document, mythical as it is, has an historical importance from its bringing in names belonging also to the traditions of Mexico proper. Thus Gucumatz, "Feathered Serpent" corresponds in name to the Mexican deity Quetzalcoatl; Túlan and the Seven Caves are familiar words in the Aztec migration traditions, and there is even mention of a chief of Toltec, a name plainly swallowed up to the famed Toltecs. Thus the legends of the Popol-Vuh confirm what is learnt from comparing the culture of Central America and Mexico proper, that, though these districts were not connected by language, the intercourse between them had been sufficient to justify the anthropologist in including both districts in one region. Historical value of the ordinary kind may be found in the latter part of the Popol-Vuh, which gives names of chiefs down to the time when they began to bear Spanish names; the great city of Quiché became the deserted ruin of Santa Cruz. The Maya district of Yucatán has also some vestiges of native traditions in the manuscript translated by D. Pio Pèrez (in Stephens, Incidents of Travel in Yucatán) and in the remarkable 16th century Relación de las cosas de Yucatán by Diego de Landa, published by Brasseur de Bourbourg (Paris, 1864). As in the Guatemalan traditions, we hear of ancient migration from the Mexican legendary region of Tula; and here the leaders are four famous chiefs or ancestors who bear the Aztec name of the Tutul-Xiu, which means "Bird-Tree." Unfortunately for the historical standing of these four ancestors, there are in the Aztec picture-writings representations of four trees, each with a bird perched on it, and placed facing the four quarters, which makes it probable that the four Tutul-Xiu of tradition may be only mythic personifications of the four cardinal points (see Schultze-Sellack in Zeitsch. f. Ethn., 1879, p. 209). Nevertheless, part of the later Maya records may be genuine—for instance, when they relate the war about three centuries before the Spanish conquest, when the king of Chichen-Itza destroyed the great city of Mayapan. Though the Central American native kings have too little interest for traditions of them to be dwelling on here, they bring to view one important historical point—that the ruined cities of this region are not monuments of a forgotten past, but that at least some of them belong to history, having been inhabited up to the conquest, apparently by the very nations who built them.

Turning now to the native chronicles of the Mexican nations, these are records going back to the 12th or 13th century, with some vague but not worthless recollections of national events from times some centuries earlier. These traditions, in some measure borne out by linguistic evidence of names, point to the immigration of detachments of a widespread race speaking a common language, which is represented by the Aztec, still a spoken language in Mexico. This language was called nahua, and one who spoke it as his native tongue was called nahualtla, so that modern anthropologists are following native precedent when they use the term Nahua for the whole series of peoples now under consideration. Earliest of the Nahua nations, the Toltecs are traditionally related to have left their northern home of Huehuetlapan in the 6th century; and there is other evidence of the real existence of the nation. Their name Tolteca signifies an inhabitant of Tollan (land of reeds), a place which has a definite geographical site in the present Tula or Tula, north of the valley of Anahuac, where a Toltec kingdom seems to have had its centre. To this nation was due the introduction of maize and cotton into Mexico, the skillful workmanship in gold and silver, the art of building on a scale of vastness still witnessed to by the mound of Cholula, said to be Toltec work, and the Mexican hieroglyphic writing and calendar. With the Toltecs is associated the tradition of Quetzalcoatl, a name which presents itself in Mexican religion as that of a great deity, god of the air, and in legend as that of a saintly ruler and civilizer. His brown and bearded worshippers describe him as of another race, a white man with noble features, long black hair and full beard, dressed in flowing robes. He came from Tula or from Yucatan (for the stories differ widely), and dwelt twenty years among them, teaching men to follow his austere and virtuous life, to hate all violence and war, to sacrifice no men or beasts on the altars, but to give mild offerings of bread and flowers and perfumes, and to do penance by the votaries drawing blood with thorns from their own bodies. Legend tells stories of his teaching men picture-writing and the calendar, and also the artistic work of the silversmith, for which Cholula was long famed; but at last he disappeared, some say towards the unknown land of Tiapullan, but others to Coatzaoclos on the Atlantic coast on the confines of Central America, where native tradition still keeps up the divine names of Gucumatz among the Quichés and Cukulcan among the Mayas, these names have the same meaning as Quetzalcoatl in Aztec, viz. "Feathered Serpent." Native tradition held that when Quetzalcoatl reached the Atlantic he sent back his companions to tell the Cholulans that in a future age his brethren, white men and bearded like himself, should land there from the sea where the sun rises and come to rule the country. That there is a basis of reality in the Toltec traditions is shown by the word tolteca having become among the later Aztecs a substantive signifying an artist or skilled craftsman. It is further related by the Mexican historians that the Toltec nation all but perished in the 11th century by years of drought, famine and pestilence, a few only of the survivors remaining in the land, while the rest migrated into Yucatan and Guatemala. After the Toltecs came the Chichimecs, whose name, derived from chichi, long, is applied to many rude tribes; they are said to have come from Amaquemecan under a king named Xolotl, names which being Aztec imply that the nation was Nahua; at any rate they appear afterwards as fusing with more cultured Nahua nations in the neighbourhood of Tezcucó. Lastly is recorded the Mexican immigration of the seven nations, Xochimilca, Chalca, Tepaneca, Acolhua, Tlahuica, Tlascalteca, Azteca. This classification of the Nahua-lac tribes has a meaning and value. It is true that Aztlán, the land whence the Aztecs traced their name and source, cannot be identified, but the later stages of the long Aztec migration seem historical, and the map of Mexico still shows the names of several settlements recorded in the curious migration map, published by Gemelli Careri (Giro del mondo, Venice, 1728) and commented on by Humboldt; among these local names are Tzompante, "place of skulls," now Zumpano in the north of the Mexican valley, and Chapultepec, "grasshopper hill," now a suburb of the city of Mexico itself, where the Aztecs are recorded to have celebrated in 1355 the festival of tying up the "bundle of years" and beginning a new cycle.

The Aztecs moving from place to place in Anahuac found little welcome from the Nahua peoples already settled there. One of the first clear events of the Aztec arrival is their being made tributary by the Tepanecs, in whose service they showed their warlike prowess in the fight near Tepeyahac, where now stands the famous shrine of Our Lady of Guadalupe. Thus they overcame the Acolhua, who had made Tezcucó a centre of prosperity. By the 13th century the Aztecs by their ferocity had barred their neighbours together against them; some were driven to take refuge on the reedy lake shore at Acoculo, while others were taken as captives into Culhuacan. The king of this district was Coxcoxtl, whose name has gained an undeserved reputation even in Europe as "Coxco, the Mexican Noah," from a scene in the native picture-writing where his name appears together with the figure of a man floating in a dug-out tree, which has been mistaken even by Humboldt for a representation of the
Mexican deluge-myth. Cozocztli used the help of the Aztecs against the Xochimilco people; but his own nation, horrified at their bloodthirsty sacrifice of prisoners, drove them out to the islands and swamps of the great salt lagoon, where they are said to have taken to making their *chivampas* or floating gardens of mud heaped on rafts of reeds and brush, which in later times were so remarkable a feature of Mexico. As one of the Aztec chiefs at the time of the founding of their city was called Tenoch, it is likely that from him was derived the name Tenochtitlan or "Stone-cactus place." Written as this name is in pictures or rebus, it probably suggested the invention of the well-known legend of a prophecy that the war-god's temple should be built where a prickly pear was found growing on a rock, and perched on it an eagle holding a serpent; this legend is still commemorated on the coins of Mexico. Mexico-Tenochtitlan, founded about 1325, for many years afterwards probably remained a cluster of huts, and the higher civilization of the country was still to be found, especially among the Acolhua in Tezcuco. The wars of this nation with the Tepanec, which went on into the 15th century, were merely destructive, but larger effects arose from the expeditions under the Culhua king Acamapichtli, where the Aztec warriors were prominent, and which extended far outside the valley of Anahuac. Especially a foray southward to Qauhnahuac, now Cuernavaca, on the watershed between the Atlantic and Pacific, brought goldsmiths and other craftsmen to Tenochtitlan, which now began to rise in arts, the Aztecs laying aside their rude garments of aloe-fibre for more finely-woven, and going out as traders for foreign merchandise. In the 16th century the last great national struggle took place. The Acolhua had at first the advantage, but Tixtilicchiti did not follow up the beaten Aztecs but allowed them to make peace, whereupon, under professions of submission, they fell upon and sacked the city of Tezcuco. The next king of Tezcuco, Nezahualcoyotl, turned the course of war, when Aczapaquizal, the Tepanec stronghold, was taken and the inhabitants sold as slaves by the conquering Acolhua and Aztecs; the place thus degraded became afterwards the great slave-market of Mexico. In this war we first meet with the Aztec name Moteuczoma, afterwards so famous in its Spanish form Montezuma. About 1430 took place the triple alliance of the Acolhua, Aztec and Tepanec kings, whose capitals were Tezcuco, Mexico and Tacopan, the latter standing much below the other two. In fact the rest of native history may be fairly called the Aztec period, notwithstanding the magnificence and culture which make Tezcuco celebrated under Nezahualcoyotl and his son Nezahualpiti. When the first Moteuczoma was crowned king of the Aztecs, the Mexican swayed extended far beyond the valley plateau of its origin, and the gods of conquered nations around had their shrines in the temple of Huitzilopochtli, the war-god of the Aztec conquerors. The rich region of Quauhnahuac became tributary; the Mixtec country was invaded southward to the Pacific, and the Xicalanca region to what is now Vera Cruz. It was not merely for conquest and tribute that the fierce Mexican ravaged the neighbouring towns, but they had a stronger motive than either in the desire to obtain multitudes of prisoners whose hearts were to be torn out by the sacrifice priests to propitiate a pantheon of gods who well personified their bloodthirsty worshippers. (E. B. T.)

**Ancient Civilization.**

While the prairie tribes of America lived under the loose sway of chiefs and councils of old men, the settled nations of Mexico had attained to a highly organized government. This may be called the government of the Aztecs; it is to be understood that the Aztecs were a part of the federation of Mexico, Tezcuco and Tacopan, where each king was absolute in his own country, but in war or other public interests they acted jointly, with powers in something like the proportion in which they were divided lands and spoils, which was two-fifths each to Mexico and Tezcuco and one-fifth to Tacopan. The successor of the Aztec king was customarily a chosen brother or nephew, the eldest having the first claim unless seen less incompeptent; this mode of succession, which has been looked on as an elaborate device for securing practical advantage, seems rather to have arisen out of the law of choice among the descendants of the female line, found in American tribes of much lower culture. Something like this appears in the succession of kings of Tezcuco and Tacopan, which went to sons by the principal wife, who was usually of the Aztec royal family. The Mexican chronicles, however, show instances of the king's son succeeding or of powerful chiefs being elected to the kingship. The term republic as it is used in reference to ancient or modern states, is not applicable to Mexico, for there was in fact a federation of four chiefs, with an assembly of nobles. In the Zapotec district the Wiyataco or high priest of Zopan was a divine ruler before whom all prostrated themselves with faces to the earth, and who would allow his foot to touch the earth, and was only seen carried in a litter. The accounts of the palaces of the native kings must be taken with some reserve, from the tendency to use descriptive terms not accurately true, but drawn from the later literature, such as from European architecture; thus what are called columns of porphyry and jasper supporting marble balconies might perhaps be better described as pillars carrying slabs, while the" doors" of the palaces must be looked on for number and extent than architectural grandeur, being but low one-storied buildings. The principal palace of Mexico consisted of hundreds of rooms ranged round three open squares, of such extent that a several weeks of travel was taken by the Mexican monarch as he wandered about till he was tired, without seeing the whole. Not less remarkable was the palace of Tezcuco, surrounded with its groves and pleasure-gardens; and, though now hardly anything remains of the buildings, the neighbouring hill of Tezozominco still has its stone steps and balustrades leading to an embankment carrying the aqueduct-channel of hewn stone which supplied water to basins cut in the solid rock still remains to prove that this was hydraulic architecture. As it is likely that many of the hieroglyphics, if highly coloured, were at any rate genuine. Till the 18th century the palace of Mexico was surrounded by a wall and his son Montezuma were to be seen carved in the porphyry hill of Chapultepec, but these as well as the hanging gardens have been destroyed, and only the groves of *ahuachete* (cypress) remain of the ancient palace, and those only through the intervention of the Jesuits. The king's garden in the middle of the field from the *tierra caliente* were transplanted, and water-fowl bred near fresh and salt pools fit for each kind, that all kinds of birds and beasts were kept in well-appointed zoological gardens, where there were homes even for alligators and snakes—all this resulted in a cultivation of natural history which was really beyond the European level of the time. From the palaces and retinues of thousands of servants attached to the royal service may be inferred at once the despotism of the government under an absolute king, whose power was the personal authority of the people; in fact some of the most remarkable of the picture-writings are tribute-rolls enumerating by hundreds and thousands the mantles, ocelot-skins, bags of gold-dust, bronze hatchets, loads of chocolate, fish, and other goods that were brought to the Court, as the tribute was a numerous and powerful class of nobles, the highest of whom (falamos) were great vassals owing little more than homage and tribute to their feudal lord, while the natural result of the unrulefulness of the nobles was that the king to keep in check increased their numbers, brought them to the capital as councillors, and balanced their influence by military and household officers, and by a rich and powerful merchant class. The nobles not only held principal, but rank, and power next to the husband of the plebeian or peasant class (macuehii). The greatest estates belonged to the king, or had been granted to military chiefs whose sons succeeded them, or were the endowments of temples, but the *calpulli* or corporate tribe, which was essentially a branch of the family, was to be held and tilled his portion of the common lands. Below the freemen were the slaves, who were war-captives, persons enslaved for punishment, or children sold by their parents. Prisoners of war were treated with much more humane consideration than those cruelly treated, retaining civil rights, and their children were born free. The superior courts of law formed part of the palace, and there were tribunals in the principal cities, over each of which presided a supreme judge or *echanalli*, who was the highest judge whose criminal decisions not even the king might reverse; he appointed the lower judges and heard appeals from them; it is doubtful whether he judged in civil cases, but both kinds of suits were known to be conducted by the judges and financial magistrates, below whom were the ward-magistrates. Lands were set apart for the maintenance of the judges, and indeed nothing gives a higher idea of the elaborate civilization of Mexico than this judicial system, which was administered in general court and council of state presided over by the king. The judicial records in picture-writings, of which some are still to be seen; sentence of death was recorded by drawing a line with an arrow across the portrait of the condemned; ancient chronicles describe the barbaric ceremony with which the king passed sentence of death, and piled the golden throne in the divine tribunal, with one hand on an ornamented skull and the golden arrow in the other. Among the resemblances to modern judicial practice is the use of a judicial oath, the witness touching the earth before the judge, in the name of the earth, by Mother Earth. The criminal laws were of extreme severity, even petty theft being punished by the thief being enslaved to the person he had robbed, while to steal a tobacco pouch or twenty ears of corn was death; he who trespassed in the garden was then and there beaten to death, and he who insulted Xipe, the god of the gold- and silver-smiths, by stealing his precious metal, was skinned alive and sacrificed to the offended deity. Though aloe-beer or "pulque" was allowed
for feasts and to inculcate moderation, and old people over seventy
seem to be represented in one of the picture-writings as having liberty of
drunkenness, young men found drunk were clubbed to death and
young women stoned. For such offences as witchcraft, fraud,
removing landmarks, and adultery the criminal had his heart cut
out of his breast; he was thrown between two stones, while lesser
punishments were harsh, such as that of plunderers, whose hair
was shaved with a pine-torch to the scalp.

Based on conquest as the Aztec kingdom was, and with the monastic
life of the church and the building of the temple in the background,
there was, above all, a fighting community. To be a tried soldier was the road
to honour and office, and the king could not be enthroned
till he had with his own hand taken captives to be butchered on
the open square, his shield blazoned with the trophies of
successful action, his prowess celebrated by songs of praise. His
men were promoted for acts of daring, and the children of
chiefs were regularly trained to war, and initiated by being sent into battle
with veterans, with whose aid the youth took his first prisoner, but his
future career depended on his being successful in some battle.

These two last-mentioned weapons have the look of highly developed
surgical instruments in some respects equal to that of an Asiatic nation,
its regular commands commanded each by its captain and provided with its
standard. The armies were very large, an expedition often consisting
of thirty thousand warriors, each numbering eight thousand men; but
the tactics of the commanders were quite rudimentary, consisting
merely of attack by arrows and javelins at a distance, gradually
closing into a hand-to-hand fight with clubs and spears, with an occasional
feigned retreat to draw the enemy into an ambush.

For convenience of plunder and escape the towns were walled and
escarp片段 strongholds on hills and in steep ravines, while
lagoon-cities like Mexico had the water approaches defended by
flotillas of boats and the causeways protected by towers and ditches;
even the smallest were fortified, the surrounding walls were forts capable of stubborn
resistance. It was held unwise to invade another nation without a solemn
embassy to warn their chiefs of the miseries to which they exposed themselves
by refusing to pay the demands of their governor, this being done
by a declaration of war, but in Mexico this degenerated into a cere-
monial farce, where tribute was claimed or an Aztec god was offered
to be worshipped in order to pick a quarrel as a pretext for an invasion
already planned to satisfy the soldiers with lands and plunder, and
to meet the priests’ incessant demands for more human sacrifices.

Among the accounts of the Mexican religion are some passages
referring to the belief in a supreme deity. The word teotl, god, has
been thought in some cases to bear this significance, but it is used in general, and
applied not only to the sun-god but to inferior gods. It is
related that Nezahualcoyotl, the poet-king of Tezcuco, built a nine-
towered temple with a starry roof above, in honour of the invisible
devil, and the idea of a serpent in thebottom of the temple,
coyoacan, "he by whom we live," who had no image, and was
proscribed, not by bloody sacrifices, but by incense and flowers.

These divinities, however, seem to have had little or no place in the popular
faith of the Aztecs, which was still largely barbaric. Tezcatlipoca was held to be the highest of these,
and at the festival of all the gods his footsteps were expected to
appear in the flour strewn to receive this sign of their coming.
He was present in the rites of the gods, and the offerings of the
people were crowded together in him. Between him and Quetzalcoatl,
the ancient deity of Cholula, there had been old rivalry. As is related in
the legends, Quetzalcoatl came into the land to teach men to till
the soil, to work metals and to rule a well-ordered state, the two gods
playing the part of opposite figures, Quetzalcoatl a god of peace and
peacefulness, Tezcatlipoca the keen spirit of enterprise and war;
the two were driven out together from the land and to the
west, beyond the ocean; thereafter they made war on one another,
suaded the weary Quetzalcoatl to drink the magic puile that sent
him roaming to the distant ocean, where he embarked in his boat
and disappeared from among men. These deities are not easily
analysed, but on the other hand Tonatiuh and Metzli, the sun and
moon, stand out distinctly as nature gods, and the traveller still sees
in the huge adobe pyramids of Teothuacan, with their sides oriented
to the four quarters, an evidence of the importance of their worship.
The war-god Huizilopochtli was the real head of the Aztec pantheon;
his idol remains in Mexico, a huge block of basil on which is sculptured
on the one side his hideous personage, adorned with the
humming-bird feathers on the left hand which signify his name, while
the not less frightful war-goddess Teyoamiqui, or "divine war-
spirit," is represented elsewhere. The fertility gods, such as
Tecunotl, god of strong drink, whose garment in grim irony cloathed
the drunkard’s corpse, and Xipe, patron of the goldsmiths,
lay beneath these were the nature-spirits of hills and groves, whose shrines were
often built in the shape of a temple. The temples were called tecalli or god’s
house, and rivalled in size as they resembled the form of
the temples of ancient Babylon. They were pyramids on a square or oblong
base, rising in successive terraces to a small summit-platform.
The great tecalli of Huizilopochtli in the city of Mexico stood in an
open space, surrounded by a wall 375 × 300 ft. at the base, and rising steeply in five terraces to the
height of 86 ft., showed conspicuously to the city the long processes
of priests and victims winding along the terraces and up to
the roof of its ceremonial platform were three-storey
-temples into whose ground-floor entered an altar and
altars, and before that of the war-god the green stone of sacrifice,
hooped up so as to bend upward the body of the victim that the priest
might more easily slash open the breast with his obsidian knife, tear
out the beating heart, and leave the head to be consumed in the flames.

Friends were waiting below for the carcass to be tumbled down
the steps for them to carry home to be cooked for the feast of victory.
Before the shrines reeking with the stench of slaughter the eternal
fires burned, "the world’s heart," with which were sacrificed
the heads of the priests and warriors. The blood of the victim
was collected in the cup, with which was offered to the gods
sacrifices; the priest was then enabled to drink the maker of a gladia-
torial fight against well-armed champions. The pyramids of Teoctistl
and Tezcatlipoca were not the only ones in the city of Mexico,
now an almost shapeless hill surmounted by a church, was about
three as long and twice as high as the teocalli of Mexico. A large
fraction of the Mexican population were set apart as priests or
warriors, and the others were divided among the many arts and
professions, such as are found elsewhere—priests, sacrifice, procession, dances,
clubs, and sports. Each had its sacred buildings:

Brasseur de Bourbourg, It is the interpretation of different mytho-
logical and historical Mexican picture-writings, composed by
an anonymous author some time after the conquest and copied by
Fernando de Alva (Ixtlilxochitl, 1568–1648). It belonged to the
priceless collection of M. de Bourbourg which was destroyed in the
18th century by Lorenzo Boturini (see his "Catalogo del Museo
historico indiano," appendix of his "Ideas de una nueva historia
general de la America septentrional, Madrid, 1746, viii, No. 13). It is
The Mexican, where published the four principal thoroughfares of
Mexico. Other copies of the same manuscript, made by Leon y Gama,
Pablo Picardo, Aubin and Brasseur, exist in the Paris National Library in the Aubin-
Goupil collection. Brasseur died before he could realize his plan
to publish the whole MS. in Nahualt with a translation. Some
parts were published by Aubin in "Anales de las prospecciones de
Mexico, and in Leon y Gama, Dos Piedras, ... , ed. Bustamente
(Mexico, 1832). Larger fragments of the Ixtlilxochitl copy were
published in the "Annales del museo nacional de Mexico, tom.
ii., Madrid, 1890; but in Part II only, and the translations
were very corrupt, and the two Spanish translations are by no means exact.
The Paris MSS. and the Ixtlilxochitl copy were carefully
studied by Dr Walter Lehmann (see Zeitschrift fur Ethnologie, 1906, pp.
365–393, and 1907, pp. 266–316), and by L. de Sarazin, in "Mexico,
vol. iii. No. 2; Dr E. Seler, Verhandlungen des XVI. Internationalen
Amerikanisten-Kongresses, Vienna, 1909, II, pp. 129–150). The precious Ixtlilxochitl copy was found by Lehmann in the library of the National Museum of Mexico, and arrangements were made for a complete edition of the work in conjunction with Professor E. Seler. Another very important MS. was discovered
by Dr Lehmann, in Guatemala. It is the MS. of Father Francisco
Ximenes, Historia de la Provincia de San Vicente de Chapa and
Guatemala, in three big volumes in folio, which contains the famous
Spanish translation of the Quiché myths or the "Popol-Vuh.

The MS. was bought at the expense of the duke of Loubat, who
decided to present it, after the death of Dr Lehmann, to the Royal
Library at Berlin.

1 One of the most important sources for the ancient Mexican
traditions and myths is the so-called "Codex Chimalpopoca," a
manuscript in the Mexican language discovered by the Abbé
chants, fasting and other austerities, but there are some peculiarities of detail. Prayers and other formulas have been copied down by Sahagun and other chroniclers, of endless prolixity, but not without occasional touches of pathos. These prayers seem essentially genuine; indeed, there is no European model from which they could have been imitated; but at the same time it must be remembered that they come down in Spanish writing, and not untouched by Spanish influence, as in one passage where there is a mention of sacred stones, which appear to have been derived from the same source as the Chaldean zodiac, in which they were combined with other objects, picture-writing, weaving, writing, and with stones, used in the Mexican calendar of religious festivities for the Mexican year has been preserved. Each 20-day period had one or more such celebrations. In the month of "diminishing of waters" the religious period set down by Sahagun was followed with a festival in which the priests with music of flutes and trumpets carrying on plumed litters infants with painted faces, in gay clothing with coloured paper wings, to be sacrificed on the mountains or in a whirlpool in the lake in sacrifice of children. The priests lacerated the flesh of the victims and threw it on the fire. This way of conducting the ritual act of devotion is within the similar practices of devotees in India. The calendar of religious festivals for the Mexican year has been preserved. Each 20-day period had one or more such celebrations. In the month of "diminishing of waters" the religious period set down by Sahagun was followed with a festival. Picture-writing, which they used systematically as a means of recording religious festivals and legends, as well as keeping accounts, was adapted to the needs of the holy days and the cycle of events which occurred in them. Facsimiles of several of these interesting translations, may be seen in Kingsborough; splendid reproductions of the beautiful Mexican and Mixtec-Zapoteco codices might be shown published at the expense of the duke of Loubat and by the "Juntas Colónicas." (Mexico, 1892) Gods are represented with their appropriate attributes—the fire-god hurling his spear, the moon-goddess with a shell, &c.; the scenes of human life are pictures of warriors fighting, of races being run, of crops being cultivated, of weaving, &c. An important step towards written poetry appearing in the picture-names of places and persons. The simplest forms of these depict the objects signified by the name, as where Chapul-lepec a name of a place, is here rendered as "a building, house, or hill;" or a stone with a cactus on it stands for Tenoch or "stone-cactus," the founder of Tenochtitlan. The system had, however, risen a stage beyond this when objects were represented, not there being a direct connection of form of object to name, but to the manner in which the Egyptian hieroglyphs passed into phonetic signs is remarkable, and writing might have been invented anew in Mexico had it not been for the Spanish conquest. The Aztec writings were vigintioctoginta, and their system of notation was depicted by dots or circles up to 20, which was represented by a flag, 400 (a score of scores) by a feather, and 8000 (a score of scores of scores) by a purse; but for convenience these symbols might be halved and quartered, so that a given symbol, whether represented by one suit of feathers, one flag, one-half of a flag, and four dots. The Mexican calendar depended on the combination of numbers with picture-signs, of which the four principal were the rabbit, reed, flint, house—tocli, acatl, tecpatl, calitl. The cycle of 52 years was reckoned by combining these signs in rotation with numbers up to 13, thus: 1 rabbit, 2 reed, 3 flint, 4 house, 5 rabbit, 6 reed, &c. &c. By accident the Mayan calendar may have been constructed by cast astral, which was laid out in rotation of the four suits, as, ace of hearts, 2 of spades, 3 of diamonds, 4 of clubs, 5 of hearts, 6 of spades, &c. In the Mexican ritual calendar of the days of the year, the same method of selection was employed. These twenty-day-sings being combined in rotation with numbers up to 13; thus, the 52 years 260, a series of nine other signs are affixed in addition, to make up the 365-day year. It is plain that this rotation of signs served no useful purpose whatever, being less convenient than ordinary counting, its main object was the combined use of numbers, and its several series of signs are thus combined to reckon years, months, and days; for instance, the Mongol cycle of 60 years is recorded by the zodiac or series of 12 signs—moose, bull, tiger, &c., combined in rotation with the five male and female elements—fire, earth, iron, water, wood; as "male-fire-bull" year, &c. This comparison is worked out in Humboldt's "Vues des Cordillères," as evidence of Mexican civilization being borrowed from Asia. Naturally the Mexican calendar-system lent itself to magic in the same way as the zodiac-signs of the Old World, each person's fate being affected by the qualities of the signs he was born under, and the astrologer-priests being called in to advise on every event of life. Of all the Roman gods, the one they put in the calendar was the "year-binding," when the 52-year cycle or bundle of years came to an end. It was believed that the destruction of the world, which after the Hindu manner the Mexicans held to have already taken place, would happen again at the end of a cycle. As the time drew near, the young girls pored over the houses and put out all fire, and on the last day after sunset the priests, dressed in the garb of gods, set out in procession for the hill of Huixachtlan, there to watch for the approach of the Pleiades to the roof of the world. The Pleiades were a band of snakes, and the sacred fire on the top of the world blazed up again, and the people began with feasting and rejoicing the new cycle. Mexican education, at any rate that of the upper class, was a splendid calendar-lent itself to magic in the same way as the religious which here presents itself under a more favourable light. After the birth of a child, the tonalpouhqui or "sun-calculator" drew its horoscope from the signs it was born under, and fixed its year of life, whether a boy's or girl's, by giving it to the nurse with appropriate prayers to the gods, when a toy shield and bow were provided if it was a boy, or a toy spindle and distaff if it was a girl, and the child received its name. An interesting picture is given by Kingsborough, shows the details of the boy's and girl's education, from the time the small circles over the child show it to be three years old, and a drawing of half a tortilla or corn-cake shows its allowance for each meal; as they grow older the lads are seen beginning to carry burdens, with bundles and fish, while the girls are instructed in spinning, weaving, grind maize, and cook—good conduct being enforced by punishments of increasing severity, up to prickng their bodies with alae-thorns and holding their faces over burning chillies. The schools were under the government, and the early age boys and girls were taught by the priests to sweep the sanctuaries and keep up the sacred fires, to fast at proper seasons and draw blood for penance, and where they received moral teaching. The use of weapons was prohibited before we were entered into the army, and when we were trained to the use of weapons and sent early to learn the hardships of war; children of craftsmen were usually taught by their fathers to follow their trade; and for the children of nobles there was a religious education, based on the corresponding religious doctrines and laws. Marriages depended much, as they do still in the East, on comparison of the horoscopes of the pair to ascertain if their birth-signs were compatible. Old women were considered virgins, and the virginity of a girl was shown by her being conducted by a priest who after moral exhortations united the young couple by tying their garments together in a knot, after which they walked seven times round the fire, casting incense into it; after the marriage ceremony, the pair entered together on a four days' fast and penance before the marriage was completed. The funeral rites of the Mexicans are best seen in the ceremonies at the death of a king. The corpse laid out in state was provided by the priest with a jug of water for his journey, and the fire was kindled in each danger of the road—the place where the two mountains strike
TOGETHER, the road guarded by the great snake and the great alligator, the eight deserts and the eight hills; they gave him garments to protect him from the cutting wind, and buried a little dog by his side to carry him across the nine waters. Then the royal body was interred in a magnificent, many-paved tomb, awaiting that of the war-god, for Mexican kings were warriors; on his face was a mask of turquoise mosaic, and a green chalchihuite-stone as a heart between his lips. In older times the dead king was buried on a throne with his property and dead attendants round him. But after him came an Aztec practice of exorcism by priests who dressed the body to the funeral pyre to be burnt by the demon- dressed priests, after which the crowd of wolves and slaves were exorted to serve their lord faithfully in the next world, were sacrificed, and their blood and exhalations were carried away with the fire, and they were provided with a ghostly retinue, but their simpler funeral ceremonies are as far as they went similar to those of their monarch.

The staple food of the Mexicans before the conquest has continued with comparatively little change. Maize, beans, and Indian corn was cultivated on patches of ground where, as in the Hindu jhum, the trees and bushes were burnt and the soil used. In the meantime they were sharpened, a sharp-pointed planting stick, a wooden sled, and a broad-bladed hoe called a coatl were the simple implements. The Mexicans understood digging channels for irrigation, especially for the cultivation of the cacahuatl, from which they taught the Europeans to prepare the tejate, a pulque toddy distilled of the same. In this they acted as the English as the words cacao, or cocoa and chocolate. Other vegetables adopted from Mexico are the tomato (tomatualli) and the chilli, used as flavouring to native dishes. The maize was ground with a stone metate, spun with a spindle, and woven in a rudimentary loom without a shuttle into the mantles and breech-clouts of the men and the chemises and skirts of the women, garments of fine texture and embroidered in colours. Ornaments of gold and silver were also worn as indications of wealth and luxury, but the women wore beads called by the Spanish frijoles, and the various savoury stews still in vogue. The juice extracted by tapping the great apple before flowering was fermented into an intoxicating drink about the strength of beer, estrellita, by the Spaniards called pulque. Tobacco, smoking pipes, and the的知识性 knowledge of the things other than the precious.

Clothing and Ornaments

Clothing was of skins of woven alpalm and palm fibre, but at the time of the conquest cotton was largely cultivated in the hot lands and spun with a spindle, and woven in a rudimentary loom without a shuttle into the mantles and breech-clouts of the men and the chemises and skirts of the women, garments of fine texture and embroidered in colours. another time it extended as far as Honduras (actual department of Choluteca) and into eastern Salvador as far as the state of Chiapas in Mexico, where the Chortegoa penetrated amongst the Mixe.

The Chortega or Mague language, so closely affiliated to the Chol dialects of Chiapas, is spoken by this tribe, their number being estimated by many Indian local names. It seems that there was formerly a mutual interpenetration between Lenca, Sumo and Chortega tribes. The territories of all these tribes can be, or more exactly, calculated by the existence of Indian local names. The Mixteca country was in various places called by the names Coatepec or Coatepec, or Landa, or vela, river; the Sumo and Ulaa country by names in uet, water; the Matagalan by names in tlie, water; the Lenca by names in teque, teque and (at) quin. Such Lenca names occur on the north-eastern shore of Ululac, or the eastern side of the lake Cortes. One is to be supposed that the Lenca and Sumo tribes superseded the Chortegoa in the last century. It seems certain that the linguistic evidence admits of no doubt—that the Chortegoa had their centre in the central part of Mexico and have extended north-westwards. It is hoped that Chortegoa remains will be found in the vast territory occupied for many centuries by the Maya peoples in the Pacific part of Guatemala. These remains would, of course, be archaeological remains.

How closely related some of the Central-American nations were in institutions to the Mexicans appears, not only in their using the same peculiar weapons, but in the similarity of their religious rites; the connexion is evident in such points as their funeral, marriage and mourning rites. It is the same with the couple, or in holding an offender’s face over burning chills as a punishment; the native legends of Central America make mention of the royal ball-play, which was the same as the Mexican game of chalchi already mentioned. The consequences of this is that the town is now extinct, the platform on which it was built is now occupied by a temple of the same name, and is a temple of the old name, but the building differs from the Mexican; thus in Yucatán we find the custom of the youths sleeping in a great bachelor’s house, an arrangement common in various parts of the world, but not in Mexico; the same remains of the temple and church have been excavated in the temple of the same name as the Mexican, which is how the common custom is known in Yucatán. We have the means of comparing the personal appearance of these nations with the Mexican custom. On early sculptures, vases, &c.; and, though there does not appear any clear distinction of race-type, the extraordinary back-sloping forehead of such figures as those of the bas-reliefs of Palenque prove that the Indians of this part of the American continent are of the same race as the Mexicans. We have no means of estimating the number of the Indians here or there, but it would appear that America to an extent quite beyond any such habit in Mexico. The notion that the ruined cities were in the Central-American forests were of great antiquity and the work of extinct nations has been repeatedly mentioned. It is the same with the work of another nation highly distinct in language, yet these nations had a common system of pictorial or written characters. One specimen of a Central-American inscription may give a general idea of them all, whether it be in Yucatán, Chiapas, Guatemala and Honduras, or in other parts of the world. The carving of these nations is from the figure of a man, with the inscription that this name is habitually given to them. The crocodile, or from the painted deer skin, the tapestry of the Codex (reproduced in Kingsborough), or from the chapter of Diego de Landa where he professes to explain and translate the characters themselves. These consist of various faces, that, in sum, &c.; and, in compartments in so complex a manner that hardly two are found alike. How they conveyed their meaning, how far they pictorially represented ideas or spelt words in the different languages of the country may be seen in the examples given and any one may see that the connected description (p. 320) gives a table of a number of their elements as phonetically representing letters or syllables, but, though there may be a partial truth in his rules, they are insufficient or too erroneous to serve as a basis for deciphering the language. The decipherment of the American characters is clear, that part of them are of the same signs. Another collection of drawings appeared in 1866, with the descriptive text by Brasseur de Bourbourg, under the title Monuments anciens du Mexique. Among other and later works, including some who have deciphered, few have been more interesting, for instance, by the late American and Frost, The American Egyptians (London, 1909); H. H. Bancroft, The Native Races of the Pacific States (5 vols., New York, 1874–1876, vol. iv. is devoted to “Antiquities”); A. F. Bandeller, Report on the Mound Builders of Ohio (Washington, 1885); Ina Z. Bliss, The Mound Builders of Ohio (Washington, 1886); Olaf A. Bandeller, Teotihuacan and Fuentes de Oaxaca (Oaxaca, 1887); R. H. Holmes, Archaeological Studies among the

II—Colonial Period. 1520-1821.

The conquest of Mexico by the Spanish forces under Hernando Cortés (q.v.) in 1520, and the death of the last Aztec emperor, Guatimacua, in 1520, which was a period known as the Colonial period of Mexican history, which lasted down to the enforced resignation of the last viceroy, O’Donoju, in 1821. During these three centuries, after a brief but most unsatisfactory experience of government by audiencias (1521-1535), sixty-four viceroyalty ruled over New Spain. Of these a few were ecclesiastics: two had two terms of office; only two or three were of native birth, and their previous official life had always been passed in other parts of the Spanish dominions.

New Spain: Extent.

New Spain was one of four great viceregalies, the other three being New Granada, Buenos Aires and Peru. Its viceroyalty ruled over districts differing in status and with overlapping and conflicting authorities, some of these being appointed directly by the king of Spain, and responsible to him. New Spain in its widest meaning includes the audiencias or judicial districts of Manila, San Domingo and Guatemala, and the viceroyalty had some sort of authority over them: but in its narrower meaning it comprised the audiencia district of Mexico and the subordinate audiencia districts of Guadalajara, Michoacan, Nueva Galicia, and Sinaloa, and the viceroyalty of Chiapas and Guatemala to beyond the eastern boundary of the modern state of Texas and northward, eventually, to Vancouver’s Island.

In the course of the 18th century this came to consist of the following divisions: (1) the kingdom of Mexico, which included the peninsula of Yucatán but not the present state of Chiapas or a part of Tabasco, these belonging to Guatemala. Approximately its southern border ran from a point slightly east of Tehuantepec to the bay of Corpus Christi, and its north limit was that of the modern states of Michoacan and Guanajuato, then cutting across San Luis Potosí to a point just above Tampico. (2) The kingdom of New Galicia, including the present state of Zacatecas, Jalisco and part of San Luis Potosí. (3) The Nuevo Regno de Leon (the present state of that name). (4) The Provincias Internas, i.e. “interior” regarded from the capital, viz. Nuevo Santander (Tamaulipas, and Texas to the bay of Corpus Christi, founded 1749), the several provinces of Nuevo Biscaya or Chihuahua, Durango, Sonora with Sinaloa, Coahuila, Texas (from Corpus Christi, Bay to the mouth of the Mermenton in the present state of Louisiana), and the two Californias.

The audiencia councils also advised the viceroy in matters of administration; and, as with other officials, his career was Government subject at its close to a formal examination by a and Organization commission—a process known as “taking his residencia.” Local government till 1786 was largely in the hands of alcaldes mayores and corregidores, the latter established in 1531 to look after the Indians, and both appointed by purchase. Towns, which were to some extent founded after the conquest as centres of civilization for the Indians, were governed by civic officials appointed in the first instance by the governor of the province, but subsequently as a rule purchasing their posts.

The church rapidly supplemented the work of the conquerors. The first Franciscan mission arrived in 1524; other orders followed. The announcement of the apparition of the Virgin to an Indian near Mexico City provided a place of pilgrimage and a patrimony in Our Lady of Guadalupe; and the friars ingeniously used the hieroglyphic writing for instruction in Christian doctrine, and taught the natives trades, for which they showed much aptitude. The university of Mexico was founded in 1553. The Jesuits established themselves in 1572, devoting themselves actively to the education both of whites and of natives, and were a powerful factor in the exploring and civilizing of the northern districts. The Inquisition was introduced in 1571. With the natives south of the latitude of Tampico there was little trouble after the Mixton War (in Guadalajara) in 1540-1562, save for occasional risings in Yucatán, Tehuantepec, and in 1711 in the Nayarit mountain region west of Zacatecas, and Tamaulipas was conquered in 1748; but the wild Indians of Sonora and New Mexico gave constant trouble to the missions and outlying settlers. There were occasionally riots due to scarcity of corn (notably in Mexico itself in 1692). As in other Spanish possessions, the Negro slavery was also practised, but not by any means on a great scale, the available Negro slaves, but these were almost wholly confined to the coast regions of Vera Cruz and Acapulco, and early in the 19th century there were only some 10,000 in all.

As the Spanish conquerors brought few women, there was much mixture of races. Among the pure whites—who were practically all of Spanish extraction—there were two well-defined classes, the Gachupines or chaptones, Spaniards born in Europe, said to be so named in allusion to their spurs, from Aztec words meaning “prickers with the foot,” and the native-born or creoles: the former, though a small minority, had almost all the higher positions both in the public services and in commerce. Besides these there were five well-defined castas: mestizos (Indian and white); mulattoes ( negro and white); Zambos ( negro and Indian), who were regarded as specially vicious and dangerous; native Indians and negroes. But there were about a dozen intermediate “named varieties,” of which the salo-atras (tending away from white) and lente en l’aire (tending towards white) were the predominant so-called “castas,” who eventually passed into the Creole class, sometimes by the decree of a court. The fact that the trade route to Manila passed through Vera Cruz, Mexico City and Acapulco entailed the settlement also of a few Chinese and Malays, chiefly on the Pacific coast.

The natives were subject to tribute and kept in perpetual tutelage: divided at the conquest, with the land, as serfs of the conquerors, in repartimientos or encomiendas, they were gradually freed at an early date from their servage, and allowed to sell their labour as they pleased; they were, however, to a great extent kept in villages or settlements, compelled to cultivate land which they held for their life only, and strictly controlled by the friars or the priests. Their numbers were several times seriously reduced by the malas huais, apparently analogous to yellow fever, but not attacking the whites, and unknown before the conquest. The negroes were allowed to buy their freedom gradually at rates fixed by the judicial authorities, and slavery seems never to have been taken much hold except in the coast region.

Of the events of this period an bare outline can here be given. The term of office of the first viceroy, Antonio de Mendoza, was marked by the Mixtón War, by an attempt to suppress the encomienda system, and by a violent epidemic among the natives. Under his successor, Velasco, the measures taken for the relief of the natives provoked the landowners to a conspiracy (repressed with great severity) to set up Cortes’ son as king of New Spain. In 1568 the island of Sacrificios, near Vera Cruz, was seized by John Hawkins (q.v.), who was surprised by the Spanish fleet accompanying the new viceroy, de Almansa, and escaped with Sir Francis Drake (q.v.), but without the remaining ships of his squadron. In 1572 and 1578, however, Drake took abundant
vendence, and in 1587 Cavendish captured the Manila galleon—a success repeated in the next century.

For the next sixty years an urgent question was the prevention of floods in the capital. Situated on the lowest of four lakes, whose waters had only one small outlet from the valley, it was only 4 ft. above the level of the lowest, and was flooded on an average once in every twenty-five years. It had been protected under the native kings by a system of dikes, which were added to under the earlier viceroys, but serious inundations in 1553 and 1580 flooded the city, and the latter suggested the relief of the highest lake, that of Zumpango, by a tunnel carrying its chief affluent into a tributary of the Panuco, and so to the Atlantic. This, however, was not then undertaken, and when mooted again in 1603 was opposed as certain to involve a heavy sacrifice of Indian life. Another inundation, in 1604, suggested the transfer of the city to Tacubaya, but the landowners opposing and the city being again inundated in 1607, the Nochistongo tunnel was begun under the auspices of a Jesuit, Enrico Martinez, and roughly completed in eleven months. It passed under a depression in the mountains of the extreme north of the valley. Humboldt states that it was 6600 metres long, 33 wide and 4 high. But it did nothing for the southern lakes, so that a further system of dikes was recommended in 1614, by the Dutch engineer Adrian Boot; it was inadequate for his work and not being lined with masonry, it was found liable to be choked by falls. Repairs were suggested in 1623, and a further inundation, with great losses of life, occurred from 1629 to 1634. The removal of the city was again mooted and, though sanctioned by the king of Spain, successfully opposed by the landowners. Another flood occurred in 1645. After a disastrous attempt to enlarge the tunnel in 1675, it was eventually converted into an open cutting, but the work was not finished till 1780, and the bottom was then 29 ft. 6 in. above the level of the lowest lake. The drainage was only satisfactorily accomplished at the end of the 19th century (see below).

A negro revolt in the Vera Cruz region (1600) and an Indian rebellion in Sinaloa and Durango may be mentioned among the events of the earlier part of the 17th century. The regular and secular clergy had early come into conflict, particularly over the tithe and the control of the Indians; and in 1621, the marquis de Gelves, an energetic reformer, who as vicerey favoured the appointment of the regulars to deal with the natives, came into conflict with Archbishop Serna of Mexico, who placed the city under interdict, excommunicated the vicerey and his confratres, imprisoned the mob, and later, the bishop of Puebla, Juan de Palacios Mendoza, transferred many native congregations from the friars to secular priests, and subsequently, in 1647, came into conflict with the Jesuits, whom he excommunicated, but who eventually triumphed with the aid of the Dominicans and the archbishop. The power of the church may be judged from the petition of the Ayuntamiento of Mexico to Philip IV. (1644) to stop the foundation of religious houses, which held half the property in the country, to suspend ordinations because there were 6,000 unemployed priests, and to suppress feast days because there were at least two per week.

To check the Dutch and British corsairs the Barlovento ("windward") squadron had been set up in 1635; but the British capture of Jamaica (1655) aggravated the danger to the Spanish convoys. During the rest of the century the ports of Yucatan and Central America were frequently raided, and in 1682 Tampico suffered a like disaster; in May 1683 Vera Cruz itself was captured through stratagem by two buccaneers, Van Horn and Laurent, who plundered the town for ten days, committed shocking outrages, and escaped as the Spanish fleet arrived. In 1685-86 the Pacific coast was ravaged by Dampier and Swan, and in 1700 Woodes Rogers, with Dampier as pilot, captured the Manila treasure galleon, a feat repeated by Anson in 1743. But the European wars of the 18th century had little effect on Mexico, save that the privileges of trade given to Great Britain by the treaty of Utrecht facilitated smuggling. In the first half of the 19th century we may note the appearance, intermittently at first, of the first Mexican periodical—the Gaceta de Mexico—in 1772, a severe epidemic of yellow fever in 1776, and the establishment about 1770 of a standing army with a nucleus of Walloons and Swiss, negroes and Indians being excluded and the half-breeds admitted under restrictions. But the great event of the 18th century was the expulsion of the Jesuits from Mexico, as from the other Spanish dominions, in 1767, under orders from Charles III. They were arrested en masse on the night of the 26th of June; their goods were sequestered, and they themselves deported to Havana, then to Cadiz, Genoa, and eventually Corsica. They had done much to civilize the natives and to educate the whites, and their expulsion, which was greatly resented by the Creoles, probably tended to increase the popular discontent and prepare for the overthrow of Spanish rule.

In 1790 Don José de Galvez was sent out as special commissioner to devise reforms, with powers independent of the then vicerey, but without much immediate result. It was, however, a consequence of his work that in 1786 the provinces and kingdoms were replaced by twelve intendencias (Guadalajara, Zacatecas, Durango, Sonora, Puebla, Vera Cruz, Merida, Oaxaca, Valladolid, Guanajato, San Luis Potosi, Mexico), whose governors and mixed councils were to be responsible to the viceroys, the former alcalde mayores, mayors and corregidores, who were very corrupt, being abolished. Possibly it is from this reform that we may date the antithesis of Federals and Centralists, which is so conspicuous in the history of republican Mexico. Among the later viceroys the Conde de Revillagigedo (1785-1794) deserves mention as a progressive ruler who developed commerce and improved administration, and took the first, but very imperfect, census, on which Humboldt based his estimate of the population in 1803 at 5,840,000. The European wars of the French revolutionary period interfered with the traffic with Spain, and so relaxed the bonds of a commercial system which hampered the manu-

consisting largely of Indians, captured a stronghold at Guanajuato and even threatened the capital; but the revolutionists were defeated in 1811 at Calderon, and the leaders executed. Another priest, however, named Morelos, continued the movement, and, despite defeat in the terrible siege of Cuatla (now Morelos) on the 2nd of May 1812, raised the south, so that in the next year his forces overran most of the kingdom of Mexico and held its southern parts, and he was able to convok a congress and issue a constitution. But he also was captured, and executed at Mexico City in 1815. Though revolutionary movements still continued, by 1817 only one leader, Vincente Guerrero, was left in the field. But in March 1820 the Spanish constitution, repudiated by King Fernando VII. soon after his restoration, was restored after a military rising in Spain. It was promulgated in Mexico, and the ecclesiastics and Spaniards, fearing that a Liberal Spanish government would force on them disenchantment, toleration and other changes, induced Augustin de Iturbide, who had already been conspicuous in suppressing the risings, to take the field in order to effect what may be called a reactionary revolution.

**III. — Independent Mexico.**

Thenceforward, till the second election of Porfirio Diaz to the presidency in 1884, the history of Mexico is one of almost continuous warfare, in which Maximilian's empire is a mere episode. The conflicts, which may at first sight seem to be merely between rival generals, are seen upon closer examination to be mainly (1) between the privileged classes, i.e., the church and (at times) the army, and the mass of the other civilized population; (2) between Centralists and Federalists, the former being with the army, the church and the supporters of despotism, while the latter represent the desire for republican and local self-government. Similar conflicts are exhibited, though less continuously, by most of the other Spanish-American states, between both sides in Mexico there was government consisting of honest doctrinaires; but military leaders exploited the struggles in their own interest, sometimes taking each side successively, and the instability was intensified by the extreme poverty of the peasantry, which made the soldiery reluctant to return to civil life, by the absence of a regular middle class, and by the concentration of wealth in a few hands, so that a revolutionary chief was generally sure both of money and of men. But after 1884 under the rule of Diaz, the Federal system continued in name, but it concealed in fact, with great benefit to the nation, a highly centralized administration, very intelligent, and on the whole both popular and successful—a modern form of rational despotism.

Iturbide eventually combined with Guerero, and proclaimed the "Plan of Iguala," which laid down, as the bases of the new state, the maintenance of the Roman Catholic religion and the privileges of the clergy, the establishment of a limited monarchy, and equality of rights for Spaniards and native-born Mexican Indians. Iturbide sought the cooperation of the viceroy Apodaca, who, however, refused; but he was presently superseded by General O’Donojó, who, being unable to get beyond Vera Cruz, recognized the independence of Mexico. O’Donojó shortly afterwards died; the Spanish government repudiated his act; and Spanish troops held the fortress of San Juan de Ulúa, off Vera Cruz, till 1827. A provisional Junta, nominated by Iturbide, issued a declaration of independence (Oct. 21, 1821), and nominated a regency of five, with Iturbide as its president. The first Mexican Congress met on the 24th of February 1822. A session of it favoured a republic; another, monarchy under Iturbide; another, which was broken up by the refusal of Spain (continued until 1836) to recognize Mexican independence, monarchy under a Bourbon prince. A conflict now arose between the republican majority and Iturbide, which was settled by a military pronunciamiento in his favour, and the Congress elected him emperor. He was crowned on the 21st of July 1822. Fresh conflicts broke out between him and the Congress, and Antonio Lopez de Santa Anna, captain-general of Vera Cruz, proclaimed a republic, promising to support the Plan of Iguala. He was defeated at Jalapa and driven to Vera Cruz; but the army deserted Iturbide, who was compelled to abdicate (April 10, 1823). The Congress deported him to Italy, and granted him a pension. He returned almost immediately, on the pretext that Spain was intriguing against Mexican independence, and on landing (having been previously outlawed) was arrested and executed (July 1, 1824).

The Congress had meanwhile undone much of his work, and had divided into Federalists and Centralists, the latter largely Monarchists and Freemasons. The Federalists were strong enough to secure the adoption of a constitution (Oct. 4, 1824) modelled on that of the United States, with additional clauses, notably one declaring the Roman Catholic religion to be alone recognized. A source of abundant discord was opened by the provision that each state should contribute its quota to the Federal revenues. No proper statistical basis for estimating the quotas existed, and the device gave each state a plausible reason for attempting secession on occasion. Moreover, the capital and some territory round it was made into a "Federal district"—another grievance intensifying the antagonism of the state to the central power. The Freemasons had been largely instrumental in overthrowing Iturbide; they now divided into the Escoceses (lodges of the Scottish ritual), who were Monarchist and Centralist, and the Yorkinos, who took their ritual from New York, and their cue, it was alleged, from the American minister, Joel Poinsett. An attempt at revolt, headed by Nicolas Bravo, vice-president, the Grand Master of the Escoceses, was suppressed, but dissensions ensued in the Yorkino party between the followers of President Guerrero (a man largely of native blood, and the last of the revolutionary leaders) and of Gomez Pedraza, the war minister. A conflict broke out, the Guerriets were victorious, and the pillage of foreign shops in Mexico City (1828), among them that of a French baker, gave a basis for the foreign claim which, ten years later, caused the "Pastry War" with France. Meanwhile, attacks on Spanish ships off Cuba by a Mexican squadron, commanded by an American, David Porter, had induced Spain to send an expedition to reconquer Mexico (1829) which was checked at Tampa by Santa Anna. During the invasion Vice-President Antonio Bustamante declared against President Guerrero; the bulk of the army supported him. Guerrero was deposed, and his partisans in the south were defeated at Chipancingo (Jan. 2, 1831); and Guerrero, retiring to Acapulco, was enticed on board an Italian merchant-ship, and treacherously seized, tried and executed (Jan.–Feb. 1834). Next year, however, a revolt broke out against Bustamante, which was joined by Santa Anna, and eventually resulted in a pronunciamento in favour of Gomez Pedraza. He, and his successor, Vice-President Gomez Farias (1833), assailed the exemption of the clergy and military officers from the jurisdiction of the civil courts, and the latter attempted to legitimate higher education and relax monastic bonds. Santa Anna took advantage of the situation to assume the presidency. He eventually became dictator, dissolved Congress (May 31, 1834) and the state legislatures, and substituted creatures of his own for the governors of the states and mayors of towns, then retiring into private life. A new Congress, having resolved itself into a constituent assembly, followed up this Centralist policy (Dec. 30, 1836) by framing a new constitution, the Siete Leyes or Seven Laws, which converted the states into departments, ruled by governors appointed by the central authority, and considerably reduced popular representation. Antonio Bustamante became the first president under it. The French claims set up by the pillage of foreign shops in Mexico had, however, remained unsatisfied, and in 1838 a French fleet blockaded the coast, bombarded the fortress of San Juan de Ulúa, off Vera Cruz, and occupied the town. The Mexican government gave way, threatened by Federalist risings and secessions of states, which culminated in 1841. Santa Anna appeared, nominally as a
mediator, and put forward the bases of Tacubaya (Sept. 28, 1841), abolishing all the Siete Leyes except the part relating to the judicial system, arranging for a new constituent assembly, and reserving for the president (himself) full power of re-organizing the administration. The Centralist government, after a vain attempt to defeat him by professing a more thorough Federalism, gave way to force, and Bustamante was allowed to leave the country. But the new Congress was too Federalist for Santa Anna, and he retired, leaving the reins to Nicolas Bravo, under whom a new Centralist constitution was established (1843). This expressly retained the privileges of the clergy and army, and was in some respects more anti-Liberal than that of 1836.

But new complications were now introduced by the question of Texas. Though a state of the Mexican Union, it had been settled from the United States in consequence of a land grant given by the Spanish viceroy to Stephen Austin in 1820, and had been estranged from Mexico partly by the abolition of slavery under a decree of President Guerrero, and partly by the prospect of the Centralist constitution of 1836. It then seduced. Santa Anna attempted to recover it, but failed, and the United States, under President Polk, was eventually defeated and captured by Houston at the battle of San Jacinto, and compelled to sign a treaty recognizing Texan independence, which was disavowed on his return to Mexico. A state of war thus continued nominally between Mexico and its seduced member, whose independence was recognized by England, France, and the United States. The slaveholders in the United States favoured annexation of Texas, and pressed the claims due from Mexico to American citizens, partly perhaps with the aim of forcing war. Most of these claims were settled by a mixed commission, with the king of Prussia as umpire, in 1840-41, and a forced loan was raised to pay them in 1843, which stimulated the revolt of Paredes against Santa Anna, who had returned to power in 1844. It resulted in Santa Anna's downfall, imprison-ment at Perote and eventual exile (Dec. 1844 to Jan. 1845), and the election of General José Joaquín Herrera as president. But Herrera was displaced in the last days of 1845 by a pronunciamiento in favour of Paredes, who undertook to uphold the national rights against the United States, and who was elected president on the 3rd of January 1846. Texas had meanwhile applied for admission into the American Union. The annexation, rejected in 1844 by the United States Senate, was sanctioned on the 1st of March 1845, and carried out on the 22nd of December 1845. The Mexican minister withdrew from Washington, and both sides made active preparations for war.

The United States forces were ordered by President Polk to advance to the Rio Grande in January 1846. They established a depot at Point Ysabel (behind the opening of Brazos Santiago), and erected a fort in Texas territory, commanding Matamoros, on the Mexican side of the Rio Grande. This provoked the Mexican forces into a defensive invasion of Texas, to cut the American communications with Point Ysabel. They were, however, defeated at Palo Alto (May 8) and Resaca de la Palma (May 9). There was an outburst of warlike feeling in the United States (with a counter-movement in the North), and an invasion of Mexico was planned by three routes—from Matamoros towards Monterey, from New Leon, from San Antonio de Bexar to Chihuahua, and from Fort Leavenworth to New Mexico. Importance attaches chiefly to the movements of the first force under General Zachary Taylor. During the war preparations President Paredes, suspected of intriguing to overthrow the Republic and set up a Spanish prince, had to give place to his vice-president Bravo, who in his turn gave way before Santa Anna, who was hastily recalled from his exile at Havana to assume the presidency and the conduct of the war (Aug. 1846). He was allowed by the American squadron blockading Vera Cruz to pass in without hindrance. Probably it was thought his presence would divide the Mexicans. The preparations of the United States took some months. It was not till the 5th of September 1846 that General Zachary Taylor could leave his depot at Camargo on the Rio Grande, and march on Monterey. It was taken by assault on the 23rd of September; Santa Anna was defeated at Buena Vista (near Saltillo) on the 23rd of February 1847, and forced back on San Luis Potosí. New Mexico was occupied without opposition; Chihuahua was occupied, but not held, owing to the difficulties in maintaining communications; and Upper California was seized in the autumn of 1846 by John C. Fremont, who had been exploring a route across the continent, and by the United States Pacific squadron, and made secure by the aid of the New Mexico expedition. But as Mexico still continued to fight, it was determined to reach the capital via Vera Cruz. That city was taken by General Scott after a siege and bombardment (March 7 to 9, 1847); and after winning the battle of Cerro Gordo (April 18), and a long delay at Puebla, Scott marched on Mexico City, stormed its defences against greatly superior forces, and effected an entrance after severe fighting on the 13th of September 1847. This virtually ended the war; Santa Anna was deprived of his command, and the treaty of Guadalupe Hidalgo, concluded on the 2nd of February 1848, ceded to the United States Texas, New Mexico and California; it provides for a payment of $15,000,000 by the United States to Mexico, and the assumption of liability by it for the claims of its subjects which it had hitherto been pressing against Mexico. This payment was doubtless intended to strengthen the United States' title to the conquered territory. It is generally admitted that Mexico was provoked into aggression in order that additional territory might be available for the extension of slavery.

The American forces were withdrawn in May and June 1848 after the ratification of the treaty by Mexico. Under the presidency of Herrera (1848-1851) attempts were made to restore order and the public credit. An arrangement was effected with English holders of Mexican stock; an attempt was made to carry out a consolidation of the internal debt, which failed; the army was reduced and reorganized, and the northern frontier was defended by military colonies, formed partly of civilized Seminole Indians from the United States. But the financial situation was desperate; the federal revenue, mostly from customs—which were evade by extensive smuggling—was not half the expenditure; and Indian revolts in Yucatan (1847-1849) and in the Sierra Gorda had added to the strain. Arista succeeded Herrera as president (Jan. 1851), and resigned (Jan. 1853).

After a sort of interregnum (Jan.–March 1853) Santa Anna was recalled (by a vote of the majority of the states under the Plan of Arroyoarco, on the 4th of February 1853, the result Santa Anna in Power, 1853-1854. of a pronunciamiento), and made dictator in the interests of federalism. His measures, partly in- spired by an able Conservative leader, Lucas Alaman, proved strongly Centralist: one is especially noteworthy, the establishment of the ministry of "fomento," or encouragement to public works, education, and intellectual and economic development, which is a conspicuous aid to Mexican welfare to-day. He also negotiated (at the end of 1853) the sale of the Mesilla valley (now Arizona) to the United States, but the purchase money was soon dissipated. On the 16th of December 1853 Santa Anna issued a decree making himself dictator with the title of serene highness. On the 1st of March 1854, at Ayutla in Guerrero, a section of the army under Colonel Villarreal proclaimed the Plan of Ayutla, demanding Santa Anna's deposition and the establishment of a provisional government to secure a new constitution. Among the leaders in the movement were Generals Alvarez and Cononfort, and it is said that Porfirio Diaz, subsequently president, then a young soldier, made his way to Benito Juarez, then in prison, and arranged with him the preliminaries of the revolt. It spread, and Santa Anna left the country (Aug. 1854). A Two filibustering expeditions at this time—one by William Walker, afterwards notorious in Nicaragua, in Lower California 1 Santa Anna tried to get back to politics in Mexico after Maximilian's fall, without success. He was assassinated with other exiles in 1874, and died in obscurity in 1876.
MEXICO

(Dec. 1853), the other by Count Raousset de Bouillon in Sonora (July 1854)—added to the general disorder.

The provisional president, General Carrera, proving too Centralist, was replaced by Alvarez (Sept. 24, 1855), two of whose ministers are conspicuous in later history—Ignacio Comonfort, minister of war, and Benito Juarez, minister of finance. Juarez (b. 1806) was of unmixed Indian blood. The son of a Zapotec peasant in a mountain village of Oaxaca, he was employed as a lad by a bookbinder in Oaxaca city, and aided by him to study for the priesthood. He soon turned to the law, though for a time he was teacher of physics in a small local college; eventually went into politics, and did excellent work in 1847 as governor of his native state. Juarez almost immediately secured the enactment of a law (Ley Juarez, Nov. 23, 1855) subjecting the clergy and the army to the jurisdiction of the ordinary courts. "Benefit of clergy" was the curse of Mexico. Officers and soldiers could be tried only by courts-martial, the clergy (including numbers of persons in minor orders, who were practically laymen) only by ecclesiastical courts. The proposed reform roused the Clericals to resistance. Alvarez gave place (Dec. 8, 1855) to his assistant, Comonfort, who, although a slavish anti-Clerical Liberal, he appointed a commission to consider the question of draining the valley of Mexico, which adopted the plan ultimately carried out in 1890-1900; suppressed a Clerical rising in Puebla (March 1856), which was punished by a considerable confiscation of church property; sanctioned a law releasing church land from mortmain, providing for its sale, for the benefit, however, of the ecclesiastical owners (called after its author Miguel Lerdo de Tejada, brother of the subsequent president), and a new draft constitution, largely modelled on that of the United States (Feb. 5, 1857). The clergy protested violently, and the Plan of Tacubaya (Dec. 17, 1857), which made Comonfort dictator, provided for the construction of a new constitution under his auspices. He was presently displaced by a thorough reactionary, General Zuloaga, and expelled from Mexico early in 1858; and for three years Mexico was a prey to civil war between two rival governments—the Republicans at Vera Cruz under Juarez, who, as Chief Justice of the Supreme Court, succeeded Comonfort; and the reactionaries at the capital. The latter were at first presided over by Zuloaga, who, proving incompetent, was replaced at the end of 1858 by Pezuela, who early in 1859 gave place to Miguel Miramón, a young, able and unscrupulous soldier who was shortly afterwards accepted as "constitutional" president by his party. The Juarists were defeated outside the city of Mexico twice, in October 1858 and on the 11th of April 1859.

Miramón.

On the second occasion the whole body of officers, who had surrendered, were shot with Miramón's authority, if not by his express orders, together with several surgeons (including one Englishman, Dr. Duval) (the fifty-three "martyrs of Tacubaya"). This atrocity caused great indignation in Mexico and abroad; the reactionists were divided; their financial straits were extreme, as the Juarists held all the chief ports. Juarez was recognized by the United States, and allowed to draw supplies of arms and volunteers thence; and in July 1859 he published laws suppressing the religious orders, nationalizing ecclesiastical property (of the estimated value of $15,000,000), which ended civil marriage and registration, transferring the cemeteries to civil control, and, in short, disestablishing the church. But the apparent hopelessness of any ending to the conflict, together with the frequent outrages of both parties on foreigners, afforded strong reasons for foreign intervention. Early in 1859 President Buchanan had recommended the step to Congress, which did not respond. On the 12th of December 1859 the McLean-Juarez treaty was concluded, which gave the United States a sort of disguised protectorate over Mexico, with certain rights of way for railroads over the Isthmus of Tehuantepec and between the Rio Grande and Pacific. The American Senate, however, did not ratify the treaty, and a motion for its reconsideration late in 1860 came to nothing, owing to the approach of the War of Secession.

When Napoleon III. was in captivity at Ham he dreamed of a Central America civilized and opened up to modern enterprise by a transoceanic canal; and the clerical refugees in Paris, among them Labastida, archbishop of Mexico, easily influenced the Empress Eugénie, herself a Spaniard, to interest her husband in the cause of centralized monarchy and the church: it is said that even in 1859 they had thoughts of setting up the Archduke Maximilian as ruler of Mexico.

The question of a joint intervention of Great Britain, France, Spain and Prussia was mooted between those powers in 1860. Early in 1859 the outrages on British subjects had caused the British minister to break off diplomatic relations. Forced contributions had been levied by both sides on goods or bullion, being European property, the reactionaries being the worst offenders; and there were numerous cases of murder and robbery of Europeans. At last, on the 17th of November 1860, Miramón, under the plea of necessity, seized $630,000 in specie which had been left under seal at the British Legation and was intended for the bondholders. On the 22nd of December 1860 his forces were routed by the Juarist general Ortega at Arroyozarco, and his government was overthrown.

Juarez entered Mexico City on the 11th of January 1861. He soon found that his government was held responsible to Europe for the excesses of its rival as well as its own. Miramón's government had violated the British Legation; the Spanish minister, the papal legate and the representatives of Guatemala and Ecuador were expelled from the country for undue interference on behalf of the reactionaries; the payments of the British loan were suspended by Juarez's Congress in July 1861; and various outrages had been committed on the persons and property of Europeans for which no redress could be obtained. The French chargé d'affaires, Dubois de Saligny, who had been sent out in November 1860, urged French intervention, and took up the Jecker claims. Jecker, a Swiss banker settled in Mexico, had lent Miramón's government in 1859 $750,000 (subject, however, to various deductions): in return, Miramón gave him 6% bonds of the nominal value of $15,000,000 which were ingeniously disguised as a conversion scheme. Jecker had failed early in 1860, Miramón was overthrown a few months later. Jecker's creditors were mostly French, but he still held Miramón's bonds, and above is reason to believe that he won over Dubois de Saligny by corrupt means. Intercepted correspondence (since confirmed from the archives of the Tülleries) showed that the Duc de Morny promised Jecker his patronage in return for 30% of the profits (De la Gorce, Hist. du Second Empire, IV. c. 1). An imperial decree naturalized Jecker in France, and Napoleon III. took up his claim. A convention between Great Britain, France and Spain for joint interference in Mexico was signed in London on the 31st of October 1861. A separate arrangement of the British claims was negotiated by Juarez, but rejected by the Mexican Congress, November 1861; and the assistance of the United States with a small loan was declined, Mexican territory being demanded as security. On the 14th of December Vera Cruz was occupied by Spanish troops under General Prim; the French fleet and troops arrived soon after, with instructions to seize and hold the Gulf ports and collect the customs for the three Powers till a settlement was effected; Great Britain sent ships, and landed marines. In view of the unhealthiness of Vera Cruz, the convention of Soledad was concluded with the Mexican government, permitting the foreign troops to advance to Orizaba and incidentally recognizing Mexican independence. But as the French harboured leaders of the Mexican reactionaries, pressed the Jecker claims and showed a disposition to interfere in Mexican domestic politics, which lay beyond the terms of the joint convention, Great Britain and Spain withdrew their forces in March 1862.

More troops were sent from France. Their advance was checked by Zaragoza and Porfírio Díaz in the battle of Cinco de Mayo, on the 5th of May 1862; and in September of that year 30,000 more French troops arrived under General Forey. Wintering at Orizaba, they recommenced their advance
Meanwhile Maximilian had captured Puebla (April 2) and besieged Mexico City, which fell on the 21st of June. The last anti-Juárez stronghold (Inayarit) submitted on the 20th of July 1867. A good deal of discontent existed among the republican rank and file, and Juárez's election in October to the presidency was opposed by Diaz's friends, but without success. But so soon as Juárez was elected, insurrections broke out, and brigandage prevailed throughout the following year. There were unsuccessful insurrections also in 1869 (clerical) and 1870 (Republican), but an amnesty, passed on the 13th of October 1870, helped to restore peace; trouble again arose, however, at the 1871 election, at which the candidates were Juárez, Sebastian Lerdo de Tejada and Diaz. Juárez's continued re-election was regarded as unconstitutional, and no party obtaining a clear majority, the matter was thrown into Congress, which elected him. Diaz's supporters refused to recognize him, and a revolution broke out, which went on so wildly till Juárez's death on the 18th of July 1872. Sebastian Lerdo de Tejada, as president of the Supreme Court, succeeded him, and ammunitioned the rebels, but made no further concessions. In the next year, however, laws were passed repeating in a stronger form the attacks of 1857 on the supremacy of the Church, and prohibiting monastic life. The first day of 1873 was marked by the opening of the Vera Cruz & Mexico railway. Protestant missions established themselves (with some opposition) in the country, and diplomatic relations were renewed with France and Spain (1874). But towards the close of Lerdo de Tejada's term he was suspected of aiming at a dictatorship, and Diaz, whom he had proscribed, made preparations for a rising, then retiring to Texas. At the beginning of 1876 the revolution broke out in Oaxaca with the plan of Tuxtepec, which was adopted by Diaz, and proclaimed as the plan of Palo Blanco (March 23). Diaz's attempt to raise the north failed, and, trying to reach Vera Cruz by sea, he was recognized on the beach and captured while attempting a four-mile swim ashore. The authorities, however, made it appear that he had again jumped overboard, concealed him for some days—generally inside one of the saloon sofas—and helped him to get ashore in disguise at Vera Cruz. He then escaped to Oaxaca and raised a force. Lerdo was declared re-elected, but was overthrown by Diaz after the battle of Tecoc (Nov. 16, 1876) and forced into exile (Jan. 1877), and Diaz was declared president on the 2nd of May 1877. A law forbidding the re-election of a president till four years had elapsed from his retirement from office was passed in the autumn of that year.

Díaz refused parole, and was confined at Puebla for some months, but made his escape, and was soon in the field again.
Diaz's first presidency (1876-1880) was marked by some unsuccessful attempts at revolution notably by Escobedo from Texas in 1878, and by a more serious conspiracy in 1879. Diplomatic relations were resumed with Spain, Germany, Italy and some South American states (1877), and France (1880). There were some frontier difficulties with the United States, and with Guatemala, which revived a claim dropped since 1858 to a portion of the state of Chiapas; and there was considerable internal progress, aided by a more liberal policy of subsidies to railways and even to lines of steamships. The boundary questions were settled under President Gonzalez (1886-1888); relations with France were renewed in 1884. The claims of the railways, however, necessitated retribution on official salaries, and the president's plan for conversion of the debt raised unexpectedly and successful opposition in an ordinarily subservient Congress. At the end of 1884 Porfirio Diaz was again elected president, and was continually re-elected, the constitution being modified expressly to allow him to continue in office.

The history of Mexico from 1884 to 1910 was almost void of political strife. President Diaz's policy was to keep down disorder with a strong hand, to enforce laws; to foster railway development and economic progress; to develop native manufactures by protective tariffs; to introduce new industries, e.g., the production of silk and wine, of cocoa and quinine; to promote forestry; to improve elementary and higher education—for all which purposes the Ministerio del Fomento is a potent engine; to encourage coloniza-
tion; and, above all, to place the national credit on a sound basis. The first step in this process was a settlement of the British debt by direct arrangement with the bondholders. In 1890 the Spanish bondholders' claims were satisfactorily arranged also. In 1891 the tariff was made more protectionist. In 1893 the depreciation of silver necessitated stringent retribution; but the budget balanced for the first time during many years, the floating debt was converted, and a loan raised for the completion of the Tehuantepec Railway. After 1896 substantial annual surpluses were spent in reducing taxation and in the extinction of debt. In 1895 the floating debt was converted into a 5% debt, the bonds of which remained at a premium for 1902; in 1896 the alcabalas or interstate customs and municipal alcobas were abolished, and replaced in part by direct taxation and increased stamp duties.

The institution by Diaz of the guardias rurales, a mounted gendarmerie composed of the class who in former days drifted into revolution and brigandage, was a potent means of maintaining order, and the extension of railways and telegraphs enabled the government to cope at once with any disturbance. The old local revolutions practically disappeared. In 1886-1887 there were some disturbances in Coahuila, New Leon, Sinaloa and Tamaulipas; subsequently hardly anything was heard of such disorders except on the Texan frontier, where in 1890 Francisco Ruiz Sandoval and in 1891 Catarino Garza made incursions into Mexico. Occasionally the Church gave trouble—the presence of foreign priests was complained of; attempts to evade the law prohibiting conventual life were detected and foiled (1891, 1894); and there were Indian risings, repressed sometimes with great severity, among the Mayas of Yucatan, whose last stronghold was taken in 1891, and the Yaquis of Sonora (1898-1900). Under federal and democratic forms, Diaz exercised a strictly centralized and personal rule. He was invited to approve the candidates proposed for state governorships; in all law cases affecting the Government or political matters the judges asked his opinion; he drafted bills, and discussed their text with individual members and committees of congress. Similarly, the state legislatures, as well as the judges and municipal officers, were actually or virtually selected by the state governors, who were practically agents of the president. Now and then the old passions broke out: in September 1898 an absurd attempt to assassinate President Diaz was made by a countryman named Arroyo, but discontent with Diaz's rule was apparently confined to a small minority.¹ In 1909 indeed there were some disquieting symptoms. Owing to Diaz's age the vice-presidency had been revived in 1904, and Don Raulita Corral elected; yet at the elections of 1909 a movement arose in favor of replacing him by General Bernardo Reyes, Governor of Nuevo Leon, but he was disposed of by an official commission to study the military systems of Europe. It was, therefore, regarded as certain that, should President Diaz die in office, Señor Corral would succeed him without serious difficulty.

In foreign affairs the rule of Diaz was uneventful. There were transient disputes with the United States (1886, 1888). In 1888-1890 and 1894-1895 a boundary dispute with Guatemala became serious. But Guatemala gave way at the threat of war (Jan. 1895) and a new treaty was made (April 1, 1895). Again in 1907 there was some friction owing to the murder of a Guatemalan ex-president by a patriot in Mexico: later in the year, however, the Mexican government was active in stopping a war between its Central American neighbours. In the difficulty between England and the United States over the Venezuelan boundary (Dec. 1893) Mexico expressed strong adherence to the Monroe doctrine in the interest of both the United States and the Central American republics. And in 1897-1898 Mexico set up a large debt to France, and succeeded in its military Johnson's debt not be left wholly to the United States, but should be undertaken by all American Powers. The first Pan-American congress met in Mexico City in 1901, and the country was represented at the second, held in Río Janeiro in 1906. Mexico also took part in organizing the permanent Central American Court of Arbitration, inaugurated on the 25th of May 1908 at Cartago, Costa Rica, under the Washington treaties of December 1907, and showed readiness to associate herself with the Government of her great northern neighbour in preserving peace among the Central American States. On the 17th of October 1909 President Talt and President Diaz exchanged visits at the frontier at El Paso, Texas.

In brief, under President Diaz's rule the history of Mexico is mainly economic. In the six financial years 1893-1894 to 1899-1900 inclusive the yield of the import duties increased by upwards of 80%; the revenue from stamps over 60%, though the duties were reduced; the postal revenue from 1895-1896 to 1899-1900 rose 60%; the telegraph revenue over 75%. In 1898-1899 the total ordinary revenue of the state was $6,013,927; in 1906-1907 it had increased to $11,428,612, or by more than 90%, and though 1907-1908 was a year of depression its total revenue ($11,177,186) exceeded that of any year save its immediate predecessor. The great drainage scheme which completed the works of the 17th century by taking out the surplus waters of the southern lakes of the valley of Mexico was devised in 1856, begun under Maximilian, proceeded with intermittently till 1885, then taken up with improved plans, practically completed by 1886, and inaugurated in 1900; the harbour of Vera Cruz was finished in 1902; the Tehuantepec railway, likely to prove a formidable rival to any interoceanic canal, was opened on the 24th of January 1906. All these were the work of an English firm of contractors, the head of which was Sir Alfred Pearson. American, and later Canadian, capital and enterprise have also been very largely concerned in the development of the country; and its progress was not permanently interfered with by the earthquake of April 9th and July 9th at Acapulco, and the floods in August 1909 at Monterrey. In 1893 elementary education was reorganized, and made compulsory, secular and gratuitous. Great attention has been paid to higher education, and—at least in the hospitals—to modern sanitation and hygiene.

Authorities.—For English readers the standard work is H. H. Bancroft, Collected Works (Histories of the Pacific States, Central America, &c., vols. x.-xiv. (Mexico, 1851-1887) with vols. xv., xvi.

¹ Don Augustin Iturbide, grandson of the emperor, godson and (perhaps) at one time the destined heir of Maximilian, was turned out of the army and imprisoned in 1890 for abusing President Diaz.
² For a full account of the works see J. B. Body in Proceedings of the Institution of Civil Engineers, cxxii. 286, sqq.

MEXICO.—

MEXICO CITY

(Texas), and vol. xvii. (New Mexico, &c.). Mention may also be made of Gaston Roudier’s Histoire de Mexico (1895). Standard Mexican authorities are: C. M. de Bustamante, Cuaderno historico de la revolution mexicana, 6 vols. (Mexico, 1832-1846); Lucas Alamán, Historia de Mexico (Mexico, 1849-1852); N. de Zamudio, Historia de Mexico desde sus tiempos primitives hasta nuestros dias, 10 vols. (Barcelona, 1876-1882); J. E. Hernández y Jáuregui, Colección de documentos para la historia de la Independencia de Mexico (6 vols.), a huge and informative illustrated work, edited by Juventino Sierra, was published in Mexico City in 1890. The most detailed popular account of Mexico is Jesús María Paredes, De la historia de Mexico: su social evolución (Barcelona, 1900-1904); a useful and handy chronicle is Isaac León Compendio de la historia general de Mexico hasta el año de 1900 (Mexico and Madrid, 1920). For the colour-plates and maps, see the French edition, Histoire de Mexico, by Gaston Félix Miramon (in French) (Rome, 1886); Schmidt von Vavera, Gesch. d. Kaisers Maximilian l. (Vienna, 1903). Ulric Ralph Burke’s Life of Benito Juárez (London, 1894) is of considerable interest to students.

For Maximilian, the Blue-books on Mexican affairs contained in Accounts and Papers (presented to parliament), vol. lviii. 1862, and vol. lviii. 1863, are valuable; E. de Kérényi, La Crème de l’empire; l’empereur Maximilian, son évolution (Paris, 1876) is a highly interesting work, and is specially noteworthy; Prince Felix Salm-Salm’s Diary gives valuable information as to Maximilian’s decline and fall. Also Dela Gorce, Histoire de France, 4 vols., v. 4; J. F. Domenach, L’Empire mexicain de Maximilien (Paris, 1867), and El General Miguel Miramón (in French) (Rome, 1886); Schmidt von Vavera, Gesch. d. Kaisers Maximilian l. (Vienna, 1903). Ulric Ralph Burke’s Life of Benito Juárez (London, 1894) is of considerable interest to students.

defend its approaches against a greatly superior force. The Chalco and Xochimilco lakes, 8 or 9 m. to the southward, which are separated by a narrow ridge of land, are connected with the lower part of the city by an artificial canal, called “La Viga,” 16 m. long and 30 ft. wide, which serves as an outlet for the overflow of those lakes and as a waterway for the natives who bring in flowers and vegetables for sale. Lake Xochimilco, celebrated for its chinampas, or “floating gardens” (see MEXICO, FEDERAL DISTRICT OF), is supplied very largely by fresh-water springs opening within the lake itself, which the city has partially diverted for its own water supply. Lake Chalco is also greatly reduced in size by railway fillings and irrigation works, to the great distress of the natives who have gamed their living by fishing in its waters since long before the Spanish conquest.

The climate of the city is temperate, dry and healthful. The temperature ranges from a minimum of 35° F. in winter to a maximum of 70° in summer. The winter range is 35° to 68°, and the summer 50° to 79°. The nights are always cool. The year is divided into a wet and dry season, the former from April to September, the latter from October to March. The rainfall, however, is light, about 20 to 25 in., but, with the assistance of irrigation, it serves to sustain a considerable degree of cultivation in the neighbourhood of the city. The health of the city is not affected by the climate. With a wet, undrained subsoil and a large population of Indians and half-breeds living in crowded quarters, the death-rate has been notoriously high, though the completion of the Valley drainage works in 1900, supplemented by underground sewers in the better parts of the city, and by better sanitation, have recently improved matters. The annual death-rate per 1000 was 54 per 1000 for the Federal District in 1901, 50 in 1902, 48 in 1903, 46 in 1904, and 56 in 1905; the increase for the last-mentioned year being due to an epidemic of typhus fever.

The city is laid out with almost unbroken regularity and is compactly built—the streets running nearly with the cardinal points of the compass. The new and better residence sections are on the western side; the poorer districts are on the eastern side nearer the swampy shores of Lake Texcoco. As the name of a street changes with almost every block, according to the old Spanish custom, a list of street names is sometimes mistakenly accepted as the number of continuous thoroughfares in the city, so that it has been said that Mexico has 600 to 900 streets and alleys. An attempt was made in 1875 to rename all running east and west to be called avenidas, all running north and south calles, and all continuous thoroughfares to have but one name—but the people clung so tenaciously to the old names that the government was compelled to restore them in 1907. Outside the Indian districts of the eastern and southern outskirts, the streets are paved with asphalt and stone, lighted with electricity and gas, and served with an efficient street railway service. The political and commercial centre of the city is the Plaza Mayor, or Plaza de la Constitución, on which face the cathedral, national palace, and municipal palace. Grouped about the Plaza de Santo Domingo are the old convent and church of Santo Domingo, the court of the Inquisition now occupied by the School of Medicine, the offices of the Department of Comunicaciones, and the old custom-house (aduanas). Close by are the old church of the Jesuits and the mechanics’ school (artes y oficios) with its large and well-equipped shops. Among other well-known plazas are: Loreto, on which faces the great enclosed market of the city; Guadalupe, in the midst of hand- some private residences; San Fernando, with its statue of Vicente Guerrero; and Morelos, with its marble statue of the national hero of that name. The Paseo de la Reforma, the finest avenue of the city, is a broad boulevard extending from the Avenida Juárez south-west to Chapultepec, a distance of nearly three miles. At intervals are circular spaces, called “glorietas,” with statues (the famous bronze equestrian statue of Charles IV., and monuments to Columbus, Cuauhtemoc the last of the Aztec emperors, and Juárez). Other notable avenues are Bucareli and Juárez, and the Avenida de la Viga, which skirts the canal of that name. The principal business streets run westward from the Plaza Mayor toward the Alameda, and is known as the Calle Jaurés, or Silversmiths Street) for two squares, Calle de San Francisco for its hot springs, and Avenida de los Insurgentes along the south side of the Alameda to its junction with the Paseo de la Reforma, or public garden, ½ m. west of the Plaza Mayor, covers an area of 40 acres, and occupies the site of the old Indian market and place of execution, where occurred the first auto-da-fé in Mexico in 1574.

The great cathedral stands on or near the site of the Aztec temple (teocalli) destroyed by Cortés in 1521. The foundations were laid in 1573, the walls were completed in 1613, the roof was finished in 1622, and the edifice was dedicated in 1667, the towers were completed in 1791, and the great church was finished about 1811. It is 426 ft. in length by 197 ft. in width, and its towers rise to a height of 204 ft. Its general plan is that of a Greek cross, with two great naves and three aisles, twenty side-chapels and a magnificent high altar supported by marble columns and surrounded by a tumbaga balustrade with sixty-two tumbago statues carrying elaborate candelabra made from rich alloy of gold, silver, copper and tin. The elaborately carved choir is also enclosed by tumbaga railings made in Mexico City, weighing 26 tons. The vaulted roof is supported by twenty Doric columns, 180 ft. in height, and the whole interior is richly carved and gilded. The walls are covered with rare paintings. Standing close beside the cathedral is the house of the Archbishop, known as El Sagrario Metropolitano. The city has about sixty church edifices, including La Profesa, Loreto, Santa Teresa, Santo Domingo and San Hipólito. At the time of the secularization of Church property there were in the city—churches, convents, monasteries, &c.—many of which were turned over to secular uses.

The national palace, also on the Plaza Mayor, has a frontage of 600 ft. facing the east of the Plaza, and covers a square of 42,840 sq. yds., or nearly 10 acres. It contains the executive offices of the government and those of five cabinet ministers, interior affairs, treasury, war and justice, the senate chamber, the general courts, national museums, agricultural, &c., and the geological bureau. The palace occupies the site of the residence of Mexico City, which was destroyed by the Spaniards, and that of Hernando Cortés, which was also destroyed in 1692. It has three entrances on the Plaza, and over its main gateway hangs the "liberty bell" of an edifice run by the liberal party. On Tlayacapan, the day of the 16th of September 1810, to call the people of Dolores to arms, now run at midnight on each recurring anniversary by the president himself. The national museum, which occupies the east side of the national palace, is rich in Mexican antiquities, among which are the famous "calendar stone," supposed to be of Toltec origin, and the "sacrificial stone," which are found in the ruins of the great Teotihuacan destroyed by Cortés. Near the cathedral is the monte de Piedad, a government bank, or *savings bank,* and the church of San Pedro de los Romeros de Terrenas (conde de Regla) with £75,000, and at one time carrying on a regular banking business including the issue of banknotes. Its business is now limited to the issue of small loans on personal securities, advancing nearly £50,000 a month. The national library, which has upwards of 250,000 volumes, occupies the old St Augustine Church, dedicated in 1692 and devoted to its present use by Juárez in 1867. It contains an interesting collection of the books of Mexican celebrities. The University of San Carlos and school of fine arts (founded in 1778) likewise contains good collections of paintings and statuary.

Among other institutions are the new post office, built in 1902 and finished in 1907; the Mineria, occupied by the schools of mining and metallurgy; the national mining institute and the castle of Chapultepec; the Iturbide palace, now occupied as a hotel; the Iturbide theatre, occupied by the chamber of deputies, for which a new legislative palace was completed in 1900; the national library, starting from 1537; the new penitentiary, completed in 1900; the Panteón, with its monuments to the most celebrated Mexicans; the new general hospital; the jockey club on Plaza Guadalupe, a new university (1871) building and an old school of矿物s. The city is likewise generously provided with hospitals and asylums.

The old Spanish edifices were very solidly constructed of stone, and private residences were provided with iron gates and window guards strong enough to withstand an attack. Private houses were also provided with flat roofs (azotea) and battlements, which gave them great defensive strength, as well as a cool, secluded retreat for their inmates in the evening. The old Moorish style of building about an open court, or patio, prevails, and the living rooms of the family are on the second floor. The better residences of the old style were commonly of two stories—the ground-floor being occupied by shops, offices, stables and servants’ quarters. The more modern constructions of the Colonia Juárez and other residential districts are more attractive and pretentious in appearance, but are less solidly built.\footnote{Bandelier thinks it should be called the "Stone of the Sun."}
Mexico City

The railway connections include direct communication with one port on the Gulf coast and with two on the Pacific—lines were under construction in 1909 to two other Pacific ports—and indirect communication with two on the Gulf. The Mexican and Inter-oceanic lines connect with the Southern Pacific of the United States, and with the Southern Pacific, which is part of the Southern Pacific (from Cordoba) via the Tecuantepec line and the port of Salina Cruz. The last-mentioned line also gives indirect connection with the Southern Pacific and the Mexican Central, which runs south from Mexico City, to carry away the overflow of Lake Zumpango (7493 ft.) in the direction of the Tula, a tributary of the Papacua. The cutting was 13 m. long and is known as the Tajo de Nochitongo. It was not completed until 1789, and then it was found that the city was still subject to partial inundations, although an enormous sum of money and 20,000 lives of Indian labourers had been expended upon the work. The greatest inundation on record occurred in 1829, when its streets were covered to a depth of 3 ft. and remained flooded until 1834. In 1856 President Ignacio Comonfort invited tenders for drainage works conditional on the use of waste water from the Papacua and 15 km. long, starting from the exit of the river and turning 43 m. long, below the mean level of the city and running north to Zumpango and thence eastward into a tunnel 6 m. long, which discharges into a small tributary of the Papacua river near the village of Tetzcoguajo. The city is 308 ft. below the level of the surface. The works were inaugurated in January 1900.

For the water supply the Aztecs used the main causeway through their city as a dam to separate the fresh water from the springs of the hill from the sea water of the lake. A pipe was connected to a spring at the base of the hill of Chapultepec. The Spaniards added three other springs to the supply and constructed two aqueducts to bring the water into the city. Three other sources were added in the 18th century. The water at that time ran right through the city, and every house had its own cistern to secure a further supply from the Rio Hondo. Besides these there are 11 public and 135 private artesian wells in the city. All these sources are estimated to yield about 220 to 230 litres per head.

A considerable attention has always been given to education in Mexico, but in colonial times it was limited in scope, and to the dominant classes. The old university of Mexico, with its faculties of theology, law and medicine (founded 1551 and inaugurated 1553), continued until 1639 to be the only school of any account. In 1553, a law and medicine, which have been signally successful. The government also maintains schools of agriculture, commerce, fine arts, music, pharmacy, technology, and an admirable preparatory or secondary school. In the last 50 years many modern schools for which modern school buildings have been erected. Normal and industrial schools for both sexes are maintained, the latter (artes y oficios) performing a very important service for the poorer classes. In 1908 there were 353 government schools in the city, including 13 professional and technical schools, and nearly 200 private schools. There are also several scientific organizations and societies. The Mexican Geographical Society (Sociedad mexicana de Geografía, 1833), the Mexican Astronomical Society, the Mexican Meteorological Society, and the National History Society (instituto Mexicano de Historia) have been established. There are also the Geological Society, the Association of Engineers and Architects, and the Society of Natural History.

The electric power supply of Mexico has never been rated as a manufacturing city. However, the development of electric power, and the possibility of transmitting it for long distances, have worked a noteworthy change in this respect, and a large number of textile, food, and tobacco factories, and the largest of these electric-power plants is on the Necoaxa and Tenango rivers, in the state of Puebla, 92 m. from the city, which is designed to furnish 40,000 horse-power for industrial and lighting purposes, and a duplicate plant was decided upon in 1904. The city, in the suburb of San Lazaro, is the current being distributed by over 100 m. of underground mains in the city and many miles of overhead wires in its outskirts and suburbs. Other plants are at San Nicolás de Los Ranchos, near the Celaya road on the north and south. According to a British consul report for 1904 there were 153 manufacturing establishments in the city producing cotton, linen and silk textiles, leather, boots and shoes, tobacco and alcoholic beverages, various and refined fruits and vegetables, and Italian pastes, chocolate, starch, hats, oils, ice, pianos, and other musical instruments, matches, beds, candles, chemicals, iron and steel, printing-type, paint and varnish, glass, looking-glass, cement and artificial stones, paper, wood and straw, paper mache, carriages and explosives, white lead, perfumery, carriages and wagons, and cords.

To these should be added the furnaces and iron-working shops which add so much to the prosperity of modern Mexico. Particularly in the manufacture of the latter, the cotton mills, of which there are 13, and the cigar and cigarette factories, of which there are 10. In the suburbs, oils, chemicals, cigarettes and bricks are made at Tacuba; cotton textiles at Costreras, San Angel and Salamanca; paper and papers at Tacuba, and bronzes at Mixcoac and Coyoacan. A little farther away are the woolen mills of San Ildefonso, the paper-mills of San Rafael, and important works for the manufacture of railway rolling stock.

History.—The City of Mexico dates, traditionally, from the year 1325 or 1327, when the Aztecs settled on an island in Lake Texcoco. The Aztec name of the city was Tenochtitlán, derived either from Tenoch, one of their priests and leaders, or from tenuch, the Indian name for the "nopal," which is associated with its foundation. The modern name is derived from Mextitl, one of the names of the Aztec god of war Huitzilopochtli, which name was later applied also to the Aztecs themselves. The island settlement, which was practically a village built on islands—some of them undoubtedly artificial, and perched on stakes—grew rapidly with the increasing power and civilization of its inhabitants, who had the remains of an earlier civilization (Tula, Teotihuacán, Cholula, and other older towns) to assist in their development. About the middle of the 15th century their mud-and-rush dwellings were partly replaced by stone structures, grouped around the central enclosure of the great teocalli, and bordering the causeways leading to the mainland. The town had reached its highest development when the Spaniards appeared in 1519, when it is said to have had, including suburban towns, a total of 60,000 dwellings, representing about 360,000 inhabitants. It was at that time about 12 m. in circumference, everywhere intersected by canals, and connected with the mainland by six long and solidly constructed causeways, as shown in the plan given in the edition of Cortés's letters by M. H. Bancroft in his History of Mexico, published in San Francisco, 1883, p. 280. Allowance should be made for the habit of exaggeration among the Spanish adventurers of that time, and also for the diplomacy of Cortés in magnifying his exploits to win the favour of his king. The truth is, without doubt, that the dwellings of the lower classes were still built of reeds and mud, and covered the greater part of the city's area, otherwise it is impossible to understand how a mere handful of Spanish soldiers, without tools and explosives, could so easily have levelled it to the ground. After its almost total destruction in November 1521, Cortés employed some 400,000 natives in rebuilding the city on its former site. Since then the lake has decreased greatly in extent, its area being reduced to 173 sq. m. and its shore-line being more than 3 m. distant from the city it once surrounded. During Spanish rule the only break in the ordinary course of events was the revolt of 1695, which resulted in the destruction of the municipal buildings. The city was not much disturbed by the struggle for independence,
but it was afterwards the scene of many a revolution until the
dictatorial authority of Porfirio Díaz put an end to petty
pronunciamentos and partisan intrigues.

In the war between Mexico and the United States the most
decisive campaign was that of General Winfield Scott directed
against the Mexican capital. With the advanced guard of an
army of about 10,000 men he arrived on the 10th of August
1847 at Ayolta, on the national road 16 m. south-east of the
city; but as the approaches from this direction were very strongly
fortified he cut a new road southward along the eastern shore
of Lake Chalco and westward along the southern shore of lakes
Chalco and Xochimilco to San Augustine, where his army arrived
on the 17th and 18th of August. The city was now 10 m.
distant by a direct road to the northward, but as the village of
San Antonio, only 3 m. ahead, was strongly fortified, another
short detour was made to the westward by cutting a road through
a field of broken lava. This movement brought the Americans
to the hills of Conteras, which was held by General Valencia
with a force of some 7000 and 22 pieces of artillery, while
President Santa Anna was in the neighbourhood with reinforce-
ments numbering 12,000 or more. The Mexicans were routed
on the morning of the 20th of August after suffering heavy
losses. San Antonio was easily taken about noon of the same
day, and in the afternoon the main division of the Mexican
army was driven from the stone church and intrenchments at
Churubusco. Three days later General Scott agreed to an
armistice, but Mexico rejected the terms of peace, and hostilities
were resumed on the 7th of September. During the armistice
the American troops were quartered in and about the village
of Tacubaya, about 2½ m. west by south of the city. Near
Tacubaya, on the north by west, were some massive stone-build-
ings known as El Molino del Rey, or the King's Mill. When
attacked by the Americans under the immediate command of
General W. J. Worth in the early morning of the 8th of September
these buildings were defended by more than 10,000 Mexicans
under Generals Leon, Alvarez and Perez, and they were captured
only after a most desperate fight, which cost the Americans
787 killed and wounded and the Mexicans at least 2000 killed,
wounded, and prisoners. To enter the city by way of the
Tacubaya causeway it was still necessary for the Americans to
capture Chapultepec. This hill, defended by about 4000
Mexicans under General Nicolas Bravo, was bombarded on
the 12th of September, and was carried by assault on the 13th.
On the following day the City of Mexico surrendered. It was
then occupied by the American army under General Winfield
Scott, and held by them until the signing of the treaty of
Guadalupe-Hidalgo (May 1848).

The French intervention of 1861 led to a second occupation
by a foreign power—a French military force under General Forey
taking possession in June 1863. Maximilian, archduke of Austria,
wanted emperor of Mexico in the cathedral in
June 1864, and held possession of the capital until the 21st of
June 1867, when it was captured by General Porfirio Díaz.
Earthquake shocks are of frequent occurrence, but the city
rarely suffers any material damage. The great earthquake
shocks of the 30th and 31st of July 1900, however, caused
considerable damage in the city, and a few lives were lost.

For further description see H. H. Bancroft, History of Mexico
(6 vols., San Francisco, 1883–95); S. D. Bartlett, History of
General Valencia to the City of Mexico and Vicinity (Mexico, 1900); Thomas A. Janvier,
The Mexican Guide (3rd ed., New York, 1879); D. Charnay, Ancient
Cities of the New World (Eng. ver., New York, 1887); and the
Plan of the ciudad de México (Mexico, 1855); Diccionario
enciclopédico hispano-mexicano (Mexico, 1821–40), XIII, 740.

MEXICO, FEDERAL DISTRICT OF, a territory set apart for
the independent and exclusive use of the Mexican Federal
Government, occupying the south-eastern part of the Valley of
Mexico, and taken from and lying within the State of Mexico,
which forms its boundaries on all sides except where it touches
the state of Morelos. Pop. (1900), 540,475, largely Indian
and half-breeds; area, 463 sq. m., or accordingly to later com-
putation 1498 sq. kilom. (578 sq. m.). The district is very
irregular in outline, its greatest length (N.W. to S.E.) being 30 m.,
and its greatest breadth 25 m. It was formerly divided into one
urban municipality and four rural prefectures, but under the law
of the 26th of March 1903 it is divided into 15 municipalities,
Mexico, Guadalupe-Hidalgo, Atzcapotzalco, Tacuba, Tacubaya,
Mixcoac, Cuaúinjimalpa, San Angel, Coyocacan, Tlalpan, Xochimilco,
Milpa Alta and Ixtapalapa; the first of these comprises the
national capital and its immediate suburbs, and the other 12 the
unequal divisions of the district with a considerable number of
towns and villages. Indians and half-breeds form more than
one-half of the rural population engaged in agriculture and gardening,
beside which there is a large percentage employed in manufac-
turing industries. The government of the district is exercised by
the national executive in accordance with the organic law of 1903,
though some measure of popular government is vested in
municipal councils (ayuntamientos) elected by popular vote for
terms of four years. These councils have lost much of their
original legislative character, but they must be consulted in
matters of local importance, such as water supply, sanitary
works, and the exploitation or sale of municipal property, and
in regard to all contracts affecting the municipality. They can
vote by a two-thirds vote the execution of any contract or
administrative project, which then, at the end of four months,
if again vetoed must be taken before the President of the
Republic for adjudication. The administrative officers, who
are appointed by the national executive, consist of a governor
of the federal district, the director-general of public works,
and the president of the superior board of health. The three
form a superior council of district government which exercises
a supervisory and advisory power, "revising, confirming,
reforming or revoking the acts of each one of the members of
the council, whenever these acts are called in question." The
council also exercises a general supervision of the making of
laws. The governor represents the national government,
and has special charge of the executive and public departments,
prisons, imposition of penalties for violation of ordinances,
pensions and festivities, civil registry, street traffic, inspection
of weights and measures, and the sale of intoxicating liquors.

The director-general of public works has special charge of the water
supply, streets and roads, parks, monuments, public lighting,
drainage, street cleaning, public buildings not under federal
control, cemeteries, slaughter-houses and markets, building
operations, and all municipal or communal property. The
president of the superior board of health has charge of all
sanitary works, general sanitary inspection, the sanitary
administration of markets, slaughter-houses and cemeteries,
and the introduction of meats from other localities. The government
of the district is divided, in part, from that of the District of
Mexico in the United States, but its citizens are not dis
franchised. They elect the ayuntamientos, which exercise no
slight influence in local affairs, and, like any state, elect senators
and deputies to the National Congress.

The principal towns of the district, some of which are merely
suburbs of the capital, are Guadaloupe, Tacubaya, Tlatlap and
Mixcoac. Within the limits of the district are the
famous lakes of Xochimilco and Tezcuco, and the
causeways called the "caños," which are filled with
popular suburban resorts easily reached by the ordinary urban
tramway service. Chapultepec (Grasshopper Hill) is an isolated
hill rising 120 ft. above the level of the lake, a large area
surmounted by a fortified structure called the "Castle," containing
the summer residence of the president and the national
military school. A finely graded road leads to the summit. The
park contains a grove of old cypress trees (Taxodium distichum,
"ahuiches" by the nates), one of which is 45 ft. in circum-
ference and nearly 200 ft. high. The hill is nearly 3 m. south-west
of the city and once commanded one of its principal causeways.
The palace was built by order of the emperor Maximilian,
who planned for it the drive known as the Paseo de la Reforma. Of
the neighbouring towns Guadalupe or Guadalupe-Hidalgo (pop. 5384 in 1900),
23 m. north by east from Mexico City, near the shore of Lake Texcoco,
is chiefly known for its shrine to Our Lady of Guadalupe, who is said to have appeared
there to the Indian Juan Diego in 1531. The shrine stands on the
MEXICO, Gulf OF—MEYER, J. L.

principal plaza and is visited by many thousands of pilgrims during the year, whose pious contributions have so enriched the church that its sacred vessels, altar rails, candelabrum and other accessories are estimated to contain fifty tons of silver. The treaty of peace between Mexico and the United States was signed here on the 29th of February 1848. Tacubaya (pop. 18,342 in 1900), on the lower slopes of the Montes de las Cruces, about 5 m. west-south-west of the city, with which it is connected by rail, is noted for its fine old residences and beautiful gardens. The National Astronomical Observatory occupies a fine modern edifice. At Popolapa is an agate tree under which, according to tradition, Cortés sat and wept after his terrible retreat from the Aztec capital on the noche triste. Farther south on the lowest slopes of the mountain range are San Andrés and San Mateo, other cattle centers. On the plain 12 m. south by east of the city, is an Indian town dating long before the discovery of America. It lies in the midst of a fertile plain devoted to the production of fruit, vegetables and flowers for the city market. Its gardens are carried out on the land by floating masses of water-plants covered with soil and secured by poplar stakes, which, taking root, soon surround them with living boundaries. These remarkable and productive gardens, called chinampas, have so increased in number and extent that the lake is practically covered by them, with the exception of the waterways, which are kept open by scooping up mud from the bottom. From the lake a broad canal runs northward to the eastern suburbs of the city. It is known as the Viga, and is believed to have been opened by the Aztecs for the transportation of grain produce to their island capital.

MEXICO, GULF OF, a mediterranean gulf almost surrounded by the coasts of the United States and Mexico, and forming the northern division of the extension westward of the west Atlantic trench (see Atlantic Ocean). Its southern boundary is defined by the partly submerged ridge which extends eastwards from the peninsula of Yucatán, and on which the island of Cuba is situated: to the east it communicates directly with the Atlantic by the Strait of Florida. On the western side of Yucatán a southerly embayment is formed by the Gulf of Campeachy. The United States coast closely follows the parallel of 30° N., while the parallel of 20° N. cuts across the Gulf of Campeachy: the greatest length—Vera Cruz to Florida—is 1120 m., and greatest width—Galveston to Campeachy—680 m. The area is approximately 717,600 sq. m.

The deepest part of the Gulf of Mexico, the so-called "Sigsbee" deep, lies below the line of 2000 fathoms, between 25° and 25⅔° N., and 84⅔° to 95° W. It is widest to the west, where the breadth is about 120 m., and narrows to 25 m. at its greatest depth (2191 fathoms) between 86° and 88° W., widening again to some 80 m. farther eastward. The continental shelf is for the most part narrow: its breadth is 6 m. at Cape Florida, 120 m. along the west coast of Florida, 10 m. at the south pass of the Mississippi, 130 m. near the boundary of Texas and Louisiana, and 15 m. off Vera Cruz. The shores are low, sandy and marshy, the coast-line being frequently doubled by lagoons. There are no islands except the "Keys" of Florida and Yucatán, and Cuba. The tides in the Gulf of Mexico are of comparatively small range (springs rarely exceed 4 ft. and neaps 2½ ft.), but a remarkable feature is the exaggeration of the diurnal inequality to such an extent as almost to extinguish the semi-diurnal tide in the central part of the Gulf, giving high and low waters only once daily. The mean level of the Gulf of Mexico, formerly given as about 40 in. above that of mean sea-level at New York, but later reports on precise levellings from New York to Biloxi through St Louis describe it vaguely as "some-what higher." The current movement in the Gulf of Mexico consists of a rotational movement in the direction of the hands of a watch, the branch of the equatorial current which enters the Caribbean Sea passing into the Gulf by the Strait of Yucatán and issuing from it by the Strait of Florida as the Gulf Stream, which unites with the remainder of the northward moving water, forming the Antilles current.

From March to September the prevailing winds are the north-east trades; these undergo considerable modification on account of the configuration of the surrounding land, and the rains which accompany them are interrupted by spells of calm thick weather, and rarely by northerly winds known as Nortes del norte colorado and Cholatéros. In the colder dry season, from October to April, the climatic situation is dominated by the relatively high temperature of the surface of the gulf, causing a cyclonic inflow of air which is associated with the strong northerly winds or "northerns" prevailing on the western side, more particularly along the Mexican coast. The northerns sometimes blow with terrific force and are at times accompanied by rain. The form and position of the Gulf of Mexico exercise a profound influence on the climate of the whole of the southern and south-eastern states of the Union, and indeed of the greater part of North America.

MEYER, CHRISTIAN ERICH HERMANN VON (1801-1869), German palaeontologist, was born at Frankfort-on-the-Main, on the 3rd of September 1801. In 1832 he issued a work entitled Palaeologica, and in course of time he published a series of memoirs on various fossil organic remains: mollusca, crustacea, fishes and higher vertebrata. His more elaborate researches were those on the Carboniferous amphibia, the Permain reptiles, the Triassic amphibia and reptiles, and the reptiles of the Liasic and Jurassic epochs, and the results were embodied in his great work Zur Fauna der Vorwelt (1835-1850), profusely illustrated with plates drawn on stone by the author. He was associated with W. Dunker and K. A. Zittel in the publication of the Palaeontographica, which began in 1851. He was awarded the Wollaston medal by the Geological Society of London in 1858. He died on the 2nd of April 1869.

MEYER, HEINRICH AUGUST WILHELM (1800-1873), German Protestant divine, was born at Gtha on the 10th of January 1800. He studied theology at Jena, and eventually became (1841) pastor, member of the consistory, and superintendent at Hanover. He died on the 21st of June 1873. He is chiefly noted for his valuable Kritischegezichter Kommentar zum Neuen Testament (16 vols.), which began to appear in 1832, was completed in 1859 with the assistance of J. F. Huther, Friedrich Düsterdieck and G. K. Künemann, and has been translated into English. New editions have been undertaken by such scholars as A. B. Ritschl, B. Weiss, H. Wendt, K. F. G. Heinrici, W. Beyrich, F. B. Sieffert.

Meyer also published an edition of the New Testament, with a translation (1839) and a Latin version of the symbolical books of the Lutheran Church (1839).

He is not to be confounded with JOHANN FRIEDRICH VON MEYER (1772-1849), the senator of Frankfort, who published a translation of the Bible in 1819 (Die heilige Schrift in berichtigter Übersetzung mit kurzen Anmerkungen; 2nd ed., 1823; 3rd ed., 1855).

MEYER, JULIUS LOThAR (1830-1893), German chemist, was born on the 15th of August 1830, at Varel in Oldenburg. He was the son of a physician, and went to study medicine first at Zürich University in 1851, and then, two years later, at Würzburg, where he had R. Virchow as his teacher in pathology. The influence of C. F. W. Ludwig, under whom he studied at Zürich, decided him to devote his attention to physiological chemistry, and therefore he went, after his graduation (1854), to Heidelberg, where R. Bunsen held the chair of chemistry. There he was so influenced by G. R. Kirchhoff's mathematical teaching that he took up the study of mathematical physics at Königsberg, and in 1855 went as assistant to A. W. V. Bunsen in physics and chemistry at Breslau, where in the preceding year he had graduated as Ph. D. with a thesis on the action of carbon monoxide on the blood. In 1866 he accepted a post in the School of Forestry at Neustadt-Eberswalde, but soon moved to Carlsruhe Polytechnic. During the Franco-German campaign the Polytechnic was used as a hospital, and he took an active part in the care of the wounded. Finally, in 1876, he became professor of chemistry at Tübingen, where he died on the 11th of April 1895. His name is best known for the scale he had in the periodic classification of the elements. He noted, as did J. A. R. Newlands in England, that if they are arranged in the order of their atomic weights they fall into groups in which similar chemical and physical properties are repeated at periodic intervals; and in particular he showed that if the atomic weights are plotted
MEYER, K. F.—MEYEBER

$\delta$ ordinates and the atomic volumes as abscissae, the curve obtained presents a series of maxima and minima, the most electro-positive elements appearing at the peaks of these curves in the order of their atomic weights. His book on *Die modernen Theorien der Chemie*, which was first published in Breslau in 1864, contains a discussion of relations between the atomic weights and the properties of the elements. In 1882 he received from the Royal Society, at the same time as D. J. Mendeleeff, the Davy medal in recognition of his work on the Periodic Law. A younger brother, O. E. Meyer, became professor of physics at Breslau in 1864.

MEYER, KONRAD FERDINAND (1825–1908), Swiss poet and novelist, was born at Zürich on the 11th of October 1825. After studying law at the university, he went for considerable periods to Lausanne, Geneva and Paris, and in Italy interested himself in historical research. In 1875 he settled at Kilchberg near Zürich, was created in 1880 a doctor philosophiae honoris causa by that university, and died at Kilchberg on the 28th of November 1898. After Gottfried Keller, Konrad Meyer is the most important Swiss poet of modern times, though as a novelist he was perhaps more successful. His poetical works include *Balladen* (1867); *Romansen und Bilder* (1870); the epic poem, *Huttiens letzte Tage* (1871); and *Gedichte* (1882; 20th ed., 1901.

Among his novels must be especially mentioned *Jürg Jenatsch* (1876; 20th ed., 1894); *Der Schauspieler* (Kanis, 1878); *Der Heilige* (1880; 12th ed., 1885; English by M. von Wendheim, *Thomas von Sain*, 1885); *Die Richterin* (1885); *Die Verschwendung des Pescara* (1887); *Angela Borgia* (1901). His shorter stories were collected in two volumes in 1885 (5th ed., 1892).

See A. Reiter, Konrad Ferdinand Meyer (1886); Lina Frey, K. F. Meyer's Gedichte und Novellen (1892); K. E. Kranzlos, K. F. Meyer (1899); A. Frey, K. F. Meyer (1900); H. Kneger, K. F. Meyer: Quellen und Wendungen seiner Gedichte (1901); B. Meyer, K. F. Meyer in der Erinnerung seiner Freunde (1904); Briefwechsel von L. von Gedike und K. F. Meyer, heraus. von A. Bettelheim (1905); A. Langmessier, K. F. Meyer (1905).

MEYER, MARIE PAUL HYACINTHE (1830–1903), French philologist, was born in Paris on the 17th of January 1840. He was educated at the École des Chartes, and in 1863 was attached to the manuscript department of the Bibliothèque Nationale. In 1876 he became professor of the languages and literatures of southern Europe at the Collège de France. In 1882 he was made director of the École des Chartes, and a year later was nominated a member of the Academy of Inscriptions. He was one of the founders of the Revue critique, and a founder and the chief contributor to Romanian (1872). Paul Meyer began with the study of old Provencal literature, but subsequently did valuable work in many different departments of romance literature, and ranks as the chief modern authority on the French language. He is the author of Rapport sur les documents manuscrits de l'ancienne littérature de la France conservés dans les bibliothèques de la Grande Bretagne (1871); *Recueil d'anciens textes bas-latins, provençaux et français* (2 parts, 1874–1876); *Alexandre le Grand dans la littérature française du moyen âge* (2 vols., 1886). He edited a great number of old French texts for the Société des antiquaires de France and independently. Among these may be mentioned *Aye d'Avignon* (1861), with Guerin; *Flamenca* (1865); the *Histoire de Guillaume le Machâle* (3 vols., 1892–1902); *Rayol de Cambras* (1882), with A. Longnon; *Fragment d'une vie du Saint Thomas de Cantorbéry* (1885); *Guillaume de Barres* (1894).

MEYER, VICTOR (1848–1897), German chemist, was born at Berlin on the 8th of September 1848, and studied at Heidelberg University under W. Bunsen, H. F. M. Kopp, G. R. Kirchhoff and H. F. Helmholz. At the age of twenty he entered J. W. A. Baeyer's laboratory at Berlin, attacking among other problems that of the composition of camphor. In 1871, on Baeyer's recommendation, he was engaged by H. von Fehling as his assistant at Stuttgart Polytechnic, but within a year he left to succeed J. Wislicenus at Zürich. There he remained for thirteen years, and it was during this period that he devised his

well-known method for determining vapour densities, and carried out his experiments on the dissociation of the halogens. In 1882, on the death of W. Weitk (1844–1881), professor of chemistry at Zürich University, he undertook to continue the lectures on benzene derivatives, and this led him to the discovery of thiophen. In 1885 he was chosen to succeed Hans Hübner (1837–1884) in the professorship of chemistry at Göttingen, where stereo-chemical questions especially engaged his attention; and in 1859, on the resignation of his old master, Bunsen, he was appointed to the chair of chemistry in Heidelberg. He died on the 8th of August 1897. In recognition of his brilliant experimental powers, and his numerous contributions to chemical science, he was awarded the Davy medal by the Royal Society in 1891.

MEYEBER, GIACOMO (1791–1863), German composer, first known as Jakob Meyer Beer, was born at Berlin on the 5th of September 1791,1 of a wealthy and talented Jewish family. His father, Herz Beer, was a banker; his mother, Amalie (née Wull), was a woman of high intellectual culture; and two of his brothers distinguished themselves in astronomy and literature.

He studied the pianoforte, first under Lauska, and afterwards under Lauska's master, Clementi. When seven years old he played Mozart's Concerto in D Minor in public, and at nine he was pronounced the best pianist at Berlin. He was placed under Zelter, and then under Bernard Weber, director of the Berlin opera, by whom he was introduced to the Abbé Vogler. Vogler invited him to Darmstadt, and in 1810 received him into his house, where he formed an intimate friendship with Karl Maria von Weber, who also took daily lessons in counterpoint, fugue and extempore organ-playing. At the end of two years the grand duke appointed Meyerbeer composer to the court. His first opera, *Jephtah's Gëldibe*, failed lamentably at Darmstadt in 1811, and his second, *Wirth und Gast* (Alimelek), at Vienna in 1814. These checks discouraged him so cruelly that he feared he had missed his vocation. Nevertheless, by advice of Salierr he determined to study vocalization in Italy, and then to form a new style. But at Venice he was so captivated by Rossini that, renouncing all thought of originality, he produced a succession of seven Italian operas—*Romilda e Costanza, Semiramide riconosciuta, Eduardo e Cristina, Emma di Resburgo, Margherita d'Anjou, L'Esule de Granata* and *Il Crociato in Egitto*—which all achieved a success as brilliant as it was unexpected. Against this act of treason to German art Weber protested lamentably; and before long Meyerbeer was barred from Venice. An invitation to Paris in 1826 led him to review his position dispassionately, and he came to the conclusion that he was wasting his powers. For several years he produced nothing in public; but, in concert with Scribe, he planned his first French opera, *Robert le Diable*. This gorgeous spectacle was produced at the Grand Opéra in 1831. It was the first of its race, a grand romantic opera, with situations more theatrically effective than any that had been attempted either by Cherubini or Rossini, and with ballet music such as had never yet been heard, even in Paris. Its popularity exceeded all expectations; yet for five years Meyerbeer appeared before the public no more.

His next opera, *Les Huguenots*, was first performed in 1836. In gorgeous colouring, rhetorical force, consistency of dramatic treatment, and careful attention of individual types, it is at least the equal of *Robert le Diable*. In two points only did its interest fully short of that inspired by the earlier work. Meyerbeer had shown himself so eminently successful in his treatment of the supernatural that one regretted the omission of that element; and, more important still, the fifth act proved to be an anti-climax. The true interest of the drama culminates at the close of the fourth act, when Raoul, leaping from the window to his death, leaves Valentine fainting upon the ground. The opera now usually ends at the fourth act.

After the production of *Les Huguenots* Meyerbeer spent many years in the preparation of his next greatest works—L'Africaine and Le Prophète. The libretti of both these operas were furnished

1 Or, according to some accounts, 1794.
MEYNELL—MÉZIÈRES, P. D.

by Scribe; and both were subjected to countless changes; in fact, the story of L'Africaine was more than once entirely rewritten.

Meanwhile Meyerbeer accepted the appointment of kapellmeister to the king of Prussia, and spent some years at Berlin, where he produced Ein Feldlager in Schlesien, a German opera, in which Jenny Lind made her first appearance in Prussia. Here also he composed, in 1846, the overture to his brother Michael's drama, Struensee. But his chief care at this period was bestowed upon the worthy presentation of the works of others. He began by producing his dead friend Weber's Euryanthe, with scrupulous attention to the composer's original idea. With equal unselfishness he procured the acceptance of Riema and Der fliegende Holländer, the first two operas of Richard Wagner, who, then languishing in poverty and exile, would, but for him, have found it impossible to obtain a hearing in Berlin. With Jenny Lind as prima donna and Meyerbeer as conductor, the opera flourished brilliantly in the Prussian capital; but the anxieties materially shortened the composer's life.

Meyerbeer produced Le Prophète at Paris in 1849. In 1854 he brought out L'Étoile du nord at the Opéra Comique, and in 1859 Le Pardon de Pléermel (Dinorah). His last great work, L'Africaine, was in active preparation at the Académie when, on the 23rd of April 1865, he was seized with a sudden illness, and died on the 2nd of May. L'Africaine was produced with pious attention to the composer's minutest wishes, on the 28th of April 1865.

Meyerbeer's genius was criticized by contemporaries with widely different results. Mendelssohn thought his style exaggerated; Fétis thought him one of the most original geniuses of the age; Wagner ungratefully calls him "a miserable music-maker," and "a Jewish banker to whom it occurred to compose operas." The reality of his talent has been recognized throughout all Europe; and his name will live so long as intensity of passion and power of dramatic treatment are regarded as indispensable characteristics of dramatic music. But his work shows that these qualities, with the aid of an experienced stage-writer, may be entirely independent of genuine musical insight.

MEYNEU, ALICE CHRISTIANA (1805— ), English poet and essayist, was the daughter of T. J. Thompson. Her early life was spent chiefly in Italy, and she was educated by her father. Her first volume of verse, Preludes (1875), illustrated by her sister Elizabeth, afterwards Lady Butler, attracted little public notice, but the delicacy and beauty of the poems and especially of the sonnet "Renunciation," were warmly praised by Ruskin. She married in 1877 the well-known Roman Catholic journalist and author, Wilfrid Meynell, who became proprietor and editor ofil Vesper Register. Under W. E. Henley’s editorship she wrote regularly in prose for the National Observer, and also later for the Pall Mall Gazette, the Saturday Review, &c.

Her Poems (1893), including much of the earlier volume of Preludes, brought her at last more definitely before the public; and this was followed in 1901 by another slender book of delicate verse, Later Poems. Mrs Meynell also showed herself a fine critic of poetry by her admirable selection, The Flower of the Mind (1897), an anthology of English verse. She edited the Selected Poems (1894) of T. G. Hake, the Poetry of Pathos and Delight (1896) of her intimate friend Coventry Patmore, and the selections from Patmore in the "Muses’ Library." Her prose essays, remarkable for fineness of culture and peculiar restraint of style, appeared in successive volumes as The Rhythm of Life (1893), The Colour of Life and other Essays (1896), The Children (1897), and The Spirit of Place (1898). Later books are London Impressions (1898) and The Work of John S. Sargent (1903).

See W. Archer, Poets of the Younger Generation (1902).

MEYR, MELCHOIR (1810—1871), German poet, novelist and philosopher, was born at Ehringen on the 28th of June 1810, and died at Munich on the 22nd of April 1871. He read law and philosophy at Heidelberg and Munich. His greatest success was the Erzählungen aus dem Ries (4th ed. Leipzig, 1892), remarkable as an accurate and sympathetic picture of rural life and character. He wrote also tragedies (Hersos Albrecht, 1831; Karl der Kühne, 1862), novels (Vier Deutsche, 1861; Ewige Liebe, 1864), and, in later life, philosophical works with a strong religious tendency. Among these were Emilie (philosophical dialogues, 1863), Die Religion des Geistes (1871), Die Fortdauer nach dem Tode (1869), Die Religion und ihre jetzige Fortbildung (1871), and Gedanken über Kunst, Religion und Philosophie (1874). In these works he attempted to develop a Deistic system of philosophy. He was the author of an anonymous work entitled Geschichten mit einem Gobrin (1869).

See Melchior Meyr, Biographisches, Briefe und Gedichte, edited by Graf Bothmer and M. Carrière (Leipzig, 1874).

MEYRIFAB, a small semi-nomad tribe of Africans of Semitic stock, settled on the east bank of the Nile near Berber. Contrary to Arab custom, it is said they never marry slaves.

MÉZERAY, FRANÇOIS EUDES DE (1610—1683), French historian, was born at Rye near Argentin, where his father was a surgeon. He had two brothers, one of whom, Jean Eudes, was the founder of the order of the Eudists. François studied at the university of Caen, and completed his education at the college of Ste Barbe at Paris. His Histoire de France depuis Faramond jusqu'à Louis le Juste (3 vols., 1643—1651), is a fairly accurate summary of French and Latin chronicles. Mézeray was appointed historiographer of France, and in 1649, on the death of Vincent Voiture, was admitted to the Académie Française. His Abrégé chronologique (3 vols., 1667—1668) went through fifteen editions between 1668 and 1717; but he did not hesitate in this work to attack the financiers, with the result that his salary as historiographer was diminished by Colbert. Mézeray succeeded Conrart as permanent secretary to the Académie Française (1675), and died at Paris on the 10th of July 1683. He translated Grotius’s Traité de la religion chrétienne (1640), and a Histoire des Turcs depuis 1612 jusqu’en 1649 (1650), which is an addition to a continuation of Chalcondyles.

See Daniel de Larroque, Vie de François Eudes de Mézeray (1720); vol. xiii. of Censures du Roi by Sainte-Beuve, and Levavasseur’s Notice sur les trois frères : Jean Eudes, François Eudes, et Charles Eudes (1855).

MÉZIÈRES, PHILIPPE DE (c. 1327—1405), French soldier and author, was born at the château of Mézières in Picardy. He belonged to the poorer nobility, and first served under Lucchino Visconti in Lombardy, but within a year he entered the service of Andrew, king of Naples, who was assassinated in September 1345. In the autumn of that year he set out for the East in the French army. After the battle of Smyrna in 1346 he was made a knight, and when the French army was disbanded he made his way to Jerusalem. He realized the advantage which the discipline of the Saracens gave them over the disorderly armies of the West, and conceived the idea of a new order of knighthood, but his efforts proved fruitless. The first sketch of the order was drawn up by him in his Nova religio passiones (1367—1368; enlarged in 1386 and 1396). From Jerusalem he found his way in 1347 to Cyprus to the court of Hugo IV., where he found a kindred enthusiast in the king's son, Peter of Lusignan, then count of Tripoli; but he soon left Cyprus, and had resumed his career as a soldier of fortune when the accession of Peter to the throne of Cyprus (1358) and his recognition as king of Jerusalem induced Mézières to return to the island, probably in 1360, when he became chancellor. He came under the influence of the pious legate Peter Thomas (d. 1366), whose friend and biographer he was to be, and Thomas, who became patriarch of Constantiople in 1364, was one of the chief promoters of the crusade of 1365. In 1362 Peter of Cyprus, with the legate and Mézières, visited the princes of western Europe in quest of support for a new crusade, and when the king returned to the east he left Mézières and Thomas to represent his case at Avignon and in the cities of northern Italy. They preached the crusade throughout Germany, and later Mézières accompanied Peter to Alexandria. After the capture of this city he received the government of a third part of it and a promise for the creation of his order, but the Crusaders, satisfied by the immense booty, refused to continue the campaign. In June 1366 Mézières was...
sent to Venice, to Avignon and to the princes of western Europe, to obtain help against the Saracens, who now threatened the kingdom of Cyprus. His efforts were in vain; even Pope Urban V. advised peace with the sultan. Mézières remained for some time at Avignon, seeking recruits for his order, and writing his Vita S. Petri Thomasii (Antwerp, 1659), which is invaluable for the history of the Alexandrian expedition. The Preface and Epistola, which form the first draft of his work on the projected order of the Passion, were written at this time. Mézières returned to Cyprus in 1368, but was still at Venice when Peter was assassinated at Nicosia at the beginning of 1369, and he remained there until 1372, when he went to the court of the new pope Gregory XI. at Avignon. He occupied himself with trying to establish in the west of Europe the feast of the Presentation of the Virgin, the office of which he translated from Greek into Latin. In 1373 he was in Paris, and he was thenzechow one of the trusted counsellors of Charles V., although this king had refused to be dragged into a crusade. He was tutor to his son, the future Charles VI., but after the death of Charles V. he was compelled, with the other counsellors of the late king, to go into retirement. He lived thenceforward in the convent of the Celestines in Paris, but nevertheless continued to exert an influence on public affairs, and to his close alliance with Louis of Orleans may be put down the calamities with which the Burgundian historians covered his name. When Charles VI. freed himself from the domination of his uncles the power of Mézières increased. To this period of his life belong most of his writings. Two devotional treatises, the Contemplatio hors moritii and the Soliloquium peccatorum, belong to 1375. In 1380 he wrote his Songe du vieil pélerin, an elaborate allegorical voyage in which he described the customs of Europe and the near East, and advocated peace with England and the pursuit of the Crusade. His Oraison tragédie, largely autobiographical, was written with similar aims. In 1395 he addressed to Richard II. of England an Épître pressing his marriage with Isabella of France. The Crusade of 1396 inspired Mézières with no enthusiasm. The disaster of Nicopolis on the 28th of September 1396 justified his fears and was the occasion of his last work, the Épître lamentable et consolatoire, in which he put forward once more the principles of his order as a remedy against future disasters. Mézières died in Paris on the 29th of May 1405.

Some of his letters were printed in the Revue historique (vol. xlii.); the two Épistres just mentioned in Kervyn de Lettenhove's edition of Froissart's Chroniques (vols. xv. and xvi.). The Songe du verger or Songe du vieil pélerin, written after 1376, is sometimes attributed to him, but without definite proofs.

See Antoine Becquet, Gallicae coelestiorum congregationis monasteriae, fundationes ... (1719); the Abbé Jean Lebeuf's Mémoires de l'Académie des Inscriptions, vols. xvi. and xvi. (1752 and 1753); J. Delavie le Roulx, La France en Oriente au xiv. siècle (1866-1890); A. Mollinier, Manuel de bibliographie historique vol. iv. (1904); and especially the researches of N. Jorga, published in the Bibliothèque de l'école des hautes études vol. 110 (Paris, 1896); and the same writer's Philippe de Mézières, et la croisade au xiv. siècle (1896). Jorga gives a list of his works and of the MSS. in which they are preserved, and analyses many of them. On the Songe du verger, see P. Paris, in Mémoires vol. xvii. (1843) of the Academy of Inscriptions.

MÉZIÈRES—MEZZOTINT

MÉZIÈRES, a town of northern France, capital of the department of Ardenne, 55 m. N.E. of Reims by the Eastern railway. Pop. (1906), town, 7007; commune, 9303. The town itself, the streets of which are narrow and irregular, is situated on the neck of a peninsula formed by a loop of the Meuse. The river separates it from its suburban districts of Charleville and the town of Charleville on the north and from the suburb of Pierre on the south. Adjoining Pierre is Mohon (pop. 5874), a metallurgical town, with fortifications of the 13th and 14th centuries, as well as the citadel still dominating the town on the east, were built under Vauban's direction, but were dismantled in 1885 and 1886. Immediately to the east of the citadel runs a canal, which provides river-traffic with a short cut across the isthmus. The parish church (16th cent.) contains inscriptions commemorating the raising of the siege of Mézières in 1521 and the marriage of Charles IX. with the daughter of the emperor Maximilian II. (1570). The north and south portals, the Renaissance tower at the west end, and the lofty vaultings, are worthy of remark. The church, which suffered severely in 1870-71, has since been restored. The prefecture and the hôtel de ville, which contains several interesting pictures relating to the history of the town, belong to the 18th century. Mézières is the seat of a prefect and of a court of assizes, and there are manufactures of bicycles, and iron and steel castings for motors, railway-carriages, &c. &c.

Founded in the 13th century, Mézières was at first only a stronghold belonging to the bishops of Reims, which afterwards became the property of the counts of Rethel. The town was increased by successive immigrations of the people of Liège, flying first from the emperor Otto, and afterwards from Charles the Bold; and also by concessions from the counts of Rethel. Walls were built in the 13th century, and in 1521 it was defended against the Imperialists by the Chevalier Bayard, to whom a statue was erected in 1893. The anniversary of the deliverance is still observed yearly on the 27th of September. In 1815 the Germans were kept at bay for six weeks, and in 1871 the town only capitulated after a bombardment during which the greater part of it was destroyed.

MEZÖTŰR, a town of Hungary, in the county of Jász-Nagykun-Szolnok, 88 m. S.E. of Budapest by rail. Pop. (1900), 25,367. It possesses important potteries. Large herds of cattle are reared on the communal lands, which are productive also of wheat, rapepese and maize. Several well-attended fairs are held here annually.

MEZZANINE (It. mezzano; Fr. entretole; Ger. Zwischengeschoss), in architecture, a storey of small height introduced between two lofty storeys, or sometimes employed to allow of the introduction of two storeys equal together in height to lofty rooms on the same floor.

MEZZOFANTI, GIUSEPPE CASPAR (1774-1840), Italian cardinal and linguist, was born on the 17th of September 1774, at Bologna, and educated there. He was ordained priest in 1797, and in the same year became professor of Arabic in the university; but shortly afterwards was deprived for refusing to take the oath of allegiance to the Cisalpine Republic. In 1803 he was appointed assistant librarian of the institute of Bologna, and soon afterwards was reinstated as professor of oriental languages and of Greek. The chair was suppressed by the viceroy in 1808, but again rehabilitated on the restoration of Pius VII. in 1814, and continued to be held by Mezzofanti until his removal from Bologna to Rome in 1831, as a member of the congregation de propaganda fide. In 1833 he succeeded Angelo Mai as chief keeper of the cardinal library, and in 1838 was made cardinal and professor of studies in the Congregation. He died at Rome on the 15th of March 1849. His peculiar talent, comparable in many respects to that of the so-called "calculating boys," was not combined with any exceptional measure of intellectual power, and produced nothing of permanent value. It seems certain, however, that he spoke with considerable fluency, and in some cases even with attention to dialectic peculiarities, some fifty or sixty languages of the most widely separated families, besides having a less perfect acquaintance with many others.

See Russell, Life of the Cardinal Mezzofanti (London, 1857); A. Bellesheim, Giuseppe Cardinal Mezzofanti (Würzburg, 1880).

MEZZOTINT. During the 19th century two revolutions occurred in the British art of mezzotinto engraving—"la manière anglaise." The original defect of the method was the incapacity of the mezzotint "burr" on copper to yield as many fine impressions as other forms of engraving. To this defect was attributable the introduction, in 1823, of steel instead of the soft copper previously used—a change which, with the endeavour to avoid technical difficulties, led to the "mixed style," or combination of mezzotint with etching, and a general departure from the traditional form of the art, "pure mezzotint" on copper. The affinity of the method to painting in black and white differentiates it from other kinds of engraving, and was the distinguishing charm of the mezzotints of the 17th and 18th centuries, was for a time lost, but a revival of pure mezzotint on
copper, beginning in 1880—a return, in fact, to the mode in which the classics of the art were engraved in the time of Sir Joshua Reynolds—was made possible through the invention of soft-ground. By means of this process, copper plates are electroplated with a film of steel, renewable when worn in course of printing; and a mezzotint on copper, so protected, yields more fine impressions than if it had been engraved on steel, whilst the painter-like quality remains unimpaired.

In "pure mezzotint" the design is evolved from dark to light entirely by scraping the engraved steel plate in the proper manner. The "ground", the original "burr" of which is left untouched in the extreme darks, and no acid, etching or line-work is used in it at all. The usual short descriptions of the method are misleading, because they fail to explain that it is the ground of an ice, which is scraped away in water or smaller degree to produce the varying tints of the design. The necessity of realizing that there are two constituents in the "ground", the "burr" and the indentations out of which the "burr" is raised, is most important. The "ground" is laid, somewhat resembles a carpenter's chisel, but the blade is 3 in. wide and only about 24 in. long, whilst the cutting edge, instead of being straight, is curved in the segment of a circle. One side of the blade is bevelled in an angle of about 45°, and the other looks not unlike a piece of black velvet. The lights and semi-tones of the design are produced by subsequent scraping and burining.

Assuming that a mezzotint is to be scraped from a lady's portrait by Sir Joshua Reynolds in which a piece of black drapery crosses a white dress—the engraver begins to work on a previously laid "ground" which would print uniformly black before comingences. In the extreme darks of the black drapery the raised "burr" is left untouched by the "scraper"—a two-edged steel instrument resembling an ancient Roman knife-blade in miniature, but having a longer point. Working from dark to light, the engraver produces the varying tints by scraping in the proper manner. The "burr" is raised, or less, or more, lowering in it so that it will not hold so much ink as where it is left untouched in the extreme darks. In the highest lights of the black drapery all the raised "burr" is taken away, or the burr is so reduced that the surface of the plate reached, but as yet the engraver has not produced any tone lighter than middle tint (although he has completely modelled out the black drapery), because the indentations out of which the "burr" is in the plates hold ink in printing. In order to produce the infinite gradation of delicate tints in the white dress, or in a sky, the scraping is continued, the indentations being thus made shallower in the passages scraped, and therefore less capable of holding the wash, whilst the parts untouched by the scraping are raised to the highest lights. When the mezzotint is finished the black drapery will stand higher than the surface of the plate modelled in relief composed of the raised "burr" while all the tints of the white dress, from the lightest to the middle tint, will have been modelled and the plate, the highest lights being the deepest. The speck of light in the eye, for instance, is a pit in the plate, surrounded by a tract of more or less raised "burr", which provides the intense black of the pupil and the half tones of the other parts of the eye, which is much deeper than the gradation from the edges of adjacent darks in the course of the constant scarpings necessary to smooth and polish the depressed lights. In printing a mezzotint a non-fluid ink is thoroughly worked into the plate, and each impression of the plate, leaving as much ink as possible in the darks, the raised "burr". If the bottom of the small lights is not quite smooth, the ink sticks in the roughness and they print dark instead of light, or the printer has to wipe so hard to get the ink out of the depressed lights in he removes too much from the raised darks. In either case loss of definition and contrast of effect results. This inherent difficulty of scraping to a sharp edge caused the use of the "mixed" methods.

Mezzotint is the best form of engraving for completeness of representation, but etching is better adapted for sketching from nature or for certain compositions. The mezzotint is used for historical views, for the production of great effects in the solid tints of mezzotint, has to be imprinted by the free play of the "scraper" on the "ground", much as the painter attains it on canvas with the brush. The" mixed" method was evolved before 1680 in Holland and in England. In 1643 by Ludwig von Siegen, an officer in the service of the Landgrave of Hesse, and an amateur artist; but the work was a direct drawing on copper with an instrument of curved teeth, like a bevelled burr. The "mixed" method is a mezzotint, ground laid with the rocking-tool and scraped from dark to light in the present manner of the art. Siegen's innovation was led up to by the previous stipple work of Giulio Campagnola and James Lutuma; of course, the first use of the "mixed" method is impossible to trace.

Rupert brought the new process to England at the Restoration, and his plates, "An Act of Parliament for the Relief of the Poor", dated 1669, by William Sherwin, the first English mezzotint, bears the engraver's acknowledgment of his indebtedness to Rupert for the secrets of the method. Mezzotint continued to be practised for a while on the Continent, but the success of Sherwin in England so excited in it that it early acquired abroad the title of "la manière Anglaise", and has since become an exclusively British art. Though used for transcribing the subject-pictures of the great Italian masters, and of Rembrandt, Van Dyck, Rubens, almost every kind of subject being later engraved in it, the staple production in mezzotint has always been the portrait. Until the middle of the 18th century the tools continued somewhat archaic, causing in the prints an appearance of want of finish, which, however, was not at all in the case from reality of representation. The coarseness and unequal depth of the "grounds" offered so much resistance to freedom of execution with the "scraper" that, though the early engravers were quite as good artists as their successors, painterly touch was not conspicuous in the work until M'Ardell and the interpreters of Sir Joshua Reynolds had improved the tools and technique.

Except for the collector, therefore, the chief attraction in the prints of this period is the plates of the Italian Masters, particularly those of John Simon, John Smith and John Faber, jun., who were the principal exponents of mezzotint in the last years of the seventeenth and first half of the eighteenth centuries, lies in their long series of prints of topographical and historical subjects, and in their reputation as line engravers. A number of Dutch and German painters then practising in England, representing such interesting personages as Charles II. and Nell Gwynn, Addison and Pope, Congreve and Wycherley, Locke and the great duke of Marlborough. The "mixed" method was the method most used by Sir Joshua Reynolds and the "mixed" mezzotint was produced in the best plates after Sir Joshua Reynolds by James M'Ardell, J. R. Smith and Valentine Green, the Watsons, Dickinson, Fisher, Dixon and some others, who worked during the last half of the 18th century. The brushwork of Reynolds was more in harmony with the mezzotint method than the slighter painting technique of Gainsborough and Romney, who were much less frequently engraved, perhaps because it is the highest technical difficulty in mezzotint that a single edge line should be produced in the form of a typical Gainsborough was never successfully engraved in the method. Though professional publishers and printers existed at this time and earlier, the word "engraving" on an old print, implying that it was engraved without the "burr", is not to be trusted in mezzotints in most cases printed, published and sold their own works, and pure mezzotint, unmixed with etching, was almost exclusively the method they employed. Mezzotints were occasionally printed in colours, notably by engraving plates by George Morland, the painter, in the pure mezzotint, to correct the worn-out condition of the plates.

The departure from pure mezzotint and temporary decay of the art began when, towards the end of the eighteenth century, Edward Eden and later the younger Yolland and his followers developed the "restricted" method, notably in translations of Vandyck and Wright of Derby, began to outline the details of his plates with stipple etching in order to avoid the labour and difficulty of scraping them to a sharp edge, using the "mixed" method. Early, however, did not destroy the mystery of the rich velvety darks by etching into them. A demand then arose for longer editions than the soft copper plates would yield, and the engravers attempted to meet it by combining mezzotint with
positive line-etching throughout the work, thus shortening the labour of scraping the details, and fortifying the darks with lines sunk below the surface of the plate. The harmony of line and tone in some of the prints in this style by S. W. Reynolds and Charles Turner, after Sir Joshua, Hopper and other contemporary artists, was more convincing than the later "mixed style" of Samuel Cousins, because there was a certain artistic significance in the etched line itself apart from the mezzotint tone, but every touch of line in a mezzotint does something to destroy the painter-like quality, and a degree of finish was lost.

The same mixed method on copper was used by J. W. M. Turner in his Liber Studiorum series of landscape plates, his object being to rival the pen-and-wash drawings of Claude's Liber Veritas. Turner devoted much energy to this process so as to obtain effects of line, tone, and wash, all the engravers before mentioned, and the etched foundation of the Liber plates was too strong for the mezzotint tone, destroying the breadth of the light, the richness of the darks, and the artistic "keeping" of the whole effect. It is the grand design of Turner reflected in the plates, rather than any quality of mezzotint or etching in them, which appeals to the artist and the connoisseur. Perhaps the greatest success in harmonizing line and tone in one plate was achieved by David Lucas in his "English Landscape" series of engravings on copper after John Constable, in which he sharpened his details with the roulette, or with a slight line put in with the point of the scraper as scraping proceeded, retaining the pure "burr" in his darks. Lucas, like Samuel Cousins and his contemporaries, was more content with the more perfect copper research of the engraver introduced in 1823, and this was the cause of the chief defect of his plates, the excessive opposition of black and white. The warm general tone which assisted the picturesqueness of the 18th century mezzotint had lost its force as the result of the introduction of the ink, due to its doings to the more porous copper. Steel being harder than copper, the rocking-tool penetrated less deeply, raising less "burr," and the consequent loss of force in the darks necessitated the scraping up of the lights to a higher key to force contrast of effect, which was not always obtained by the use of very white paper and a coarse black ink. It was soon found that the unfortified "burr," even on steel, would not yield the constantly increasing numbers of impressions demanded. The labour of scraping sharp lines was greatly increased, and sharpness with some success was obtained on steel, painter-like touch was practically unattainable on it, and the general effect was cold and uninteresting.

The early work of Samuel Cousins after Lawrence in the compared pure mezzotint ceased to be practised altogether, and in 1831 he died. In 1848 he was led up to by the invention of steel-facings. The competition of photogravure, which steel-facings made a commercially possible affair, at a time checked the new movement, but a photogravure, despite a mere superficial resemblance to a mezzotint, is a photograph manipulated to imitate the effects of the metal engraving. Samuel Cousins, 1808 for the first time a Society of Mezzotint Engravers was formed to foster the art.

MFUMIBO—MIALL

MFUMIBO, or Kirunga, general names for a chain of volcanic mountains extending across the Central African, or Albertine, rift-valley immediately north of Lake Kivu. The range, the result probably of recent geological changes, completely blocks the valley at this point, forming a divide between the rivers flowing north to the Nile and the waters of Lake Kivu, connected through Tanganyika with the Congo system. The chain consists of two groups of mountains, surrounded by a vast lava field. The western group lies directly north of Lake Kivu, and contains two active volcanoes, Kirunga-cha-gongo, the nearest to the lake (11,194 ft. high), and Kirunga-namlagira (9171 ft.), some 10 m. further north. The eastern group contains several higher peaks—some rising to needle-like points, others being truncated cones. The most lofty, Katissimbi (14,683 ft.), lies in 29° 27' 20" E., 1° 30' 20" S. Mikeno, a few miles north and west of Karissimbi, is 14,835 ft. high. The most easterly of the range, Muhavuru (13,565 ft.), in 29° 40' 30" E., 1° 23' S., is an isolated sugarloaf-shaped mass with a crater filled with water on its summit. This is the mountain to which the names Mfumbiro and Kirunga were originally applied. Some 6 m. west and a little north of Muhavuru is Sabyino (Sabino), 11,881 ft. high. The eastern peaks are snowcapped for a part of the year. North of these high mountains is a district, extending towards Albert Edward Nyanza, containing hundreds of low peaks and extinct volcanoes. It is to this region that the name Umfumira or Mfumbiro is said properly to belong.

Mfumbiro, i.e., Muhavuru, was first seen by a white man in 1861, J. H. Speke, in his journey to discover the source of the Nile, obtaining a distant view of the cone, which was also seen by H. M. Stanley in 1876. By its Baganda name of Mfumbiro (cook-house mountains) it figured on the maps somewhat east of its true position, first referred to by Johann Stuhmann in 1891. In 1894 Count von Götzen travelled through the volcanic region, and the range was subsequently explored by E. S. Grogan, Major St Hill Gibbons, Captain Herrmann, Dr R. Kandt and others, the principal heights being determined in 1903.

The Anglo-German agreement of the 1st of July 1890 "Mount Mfumbiro" was included in the British sphere in East Africa.

See Captain Herrmann, "Vulkangebiet des zentralafrikanischen Grabens," in Mitteil. v. Forsch. u. Gelebten a. d. deutschen Schulzgebieten, vol. xlvii. (Berlin, 1904), and Adolf Friedrich, duke of Mecklenburg, Ins Inserire Afrika (Leipzig, 1909); both give maps.

MHOW, a town of Central India, with British military cantonment, within the native state of Indore, on the Malwa branch of the Rajputana railway, 13 m. S. of Indore. Pop. (1901), 36,639. It is the headquarters of the 4th division of the southern army, and one of the chief military stations of India. There are two high schools, a Zoroastrian and a Canadian mission, the Dorabji Pestonji dispensary, and a gaol.

MIAGAO, a town on the southern coast of the province of Iloilo, is an island of Panay, Philippine Islands, about 25 m. W.S.W. of the town of Iloilo, the capital. Pop. (1903), 26,656; in the same year the neighbouring town of San Joaquin (pop. 1903, 14,333) was incorporated with Miagao. It has a cool and healthful climate. The neighbouring country is hilly and sterile, but produces sibouco in considerable quantities. The weaving of fabrics of abacá (Musa textilis), or Manila hemp, and pineapple fibre is the most important local industry. The language is Panay-Visayan.

MIALL, EDWARD (1809—1888), English Nonconformist divine and journalist, was born at Portsmouth on the 8th of May 1809. He was Congregational minister at Ware (1831) and Leicester (1834), and in 1841 founded the Nonconformist, a weekly newspaper in which he advocated the cause of disestablishment. Miall saw that if the programme of Nonconformity was to be carried through it must have more effective representation in Parliament. One of the firstfruits of his work was the election of John Bright into parliamentary life; and by 1870 Miall was a member of the House of Commons. This was due largely to the efforts of the Anti-State Church Association, afterwards known as the Liberation Society, which Miall had founded in 1844. The long fight for the abolition of compulsory church-rates was finally successful in 1868, and then in 1870 Miall was prominent in the discussions aroused by the Education Bill. He was at this time M.P. for Bradford (1860—1874), having previously (1852—1867) sat for Rochdale. In 1874 he retired from public life, and received from his admirers a present of ten thousand guineas. He died at Sevenoaks on the 20th of April 1881.

See the Life, by A. Miall (1884).
MIAMI, a city and the county-seat of Dade county, Florida, U.S.A., in the S.E. part of the state, on the N. bank of the Miami river and on Biscayne Bay. Pop. (1900), 1681; (1905), 4733; (1910), 5417. It is served by the Florida East Coast railway and by lines of coastal steamships, and is the point of departure of the P. & O. steamships for Nassau and Havana. Miami is the centre of a farming country in which citrus fruits, especially grape-fruit, pineapples and winter vegetables are raised for northern markets. There is excellent rod-fishing; Spanish and king mackerel and blue-fish are shipped from Miami in large quantities; and in Biscayne Bay there are important sponge fisheries. An alligator "farm" and the Subtropical Laboratory of the U.S. government are points of interest. In the city is Fort Dallas (now abandoned), where American troops were quartered during the Seminole War; and Miami is still the trading point of the Seminole Indians, being immediately south of the Everglades, their home. In 1900 a project was on foot to cut a channel from Miami to Lake Okeechobee and from the other side of that lake west to the Gulf at Fort Myers, thus providing an inland waterway and draining much swampy but fertile land. In 1896 there were only two dwellings and one storehouse within the present corporate limits, but in that year the place was chosen as the southern terminal of the Florida East Coast railway, which was afterwards extended towards Key West. Soon afterwards Henry M. Flagler (b. 1830), the owner of the railway, began the construction of the magnificent Royal Palm hotel, and Miami became a popular winter resort. Then came the development of commerce by the improvement of the harbour, by donations from Mr Flagler and grants by the United States government.

MIAMI, a tribe of North American Indians of Algonquian stock. The English called them Twilightee, a corruption of the native name, which meant the cry of the crane. They were first found in south-eastern Wisconsin, and in 1764 numbered about 1750. Their civilization was advanced and they lived in stockaded towns. They took part in Pontiac's conspiracy in 1764 and in the American War of Independence and American War of 1812 they fought on the English side. At the close of this war they were greatly reduced in numbers. A few Miami still live on a reservation in Oklahoma and in Wabash county, Indiana.

MIANTONOMO ( ? -1643), chief of the Narraganset tribe of North American Indians, nephew of their grand sachem, Canonicus (d. 1647). He seems to have been friendly to the English colonists of Massachusetts and Connecticut, though he was accused of being treacherous. In 1636, when under suspicion, he was compelled to return his loyalty to the colonists. In the following year he permitted John Mason to lead his Connecticut expedition against the Pequot Indians through the Narraganset country, and in 1638 he signed for the Narraganset the tripartite treaty between that tribe, the Connecticut colonists and the Mohegan Indians, which provided for a perpetual peace between the parties, and he agreed to take under his jurisdiction eighty of the two hundred troublesome Pequot. In 1643 a quarrel broke out between the Mohegan and the Narraganset, and Miantonomo led his warriors against those of Uncas, the Mohegan sachem. He was defeated and captured at what is now Norwich, Conn., was turned over to the Connecticut authorities, and was later tried at Boston by the commissioners of the United Colonies of New England. A committee of five clergymen, to whom his case was referred, recommended that he be executed, and the commissioners accordingly sentenced him to death and chose Uncas as his executioner. Miantonomo, who was kept in ignorance of this sentence, was taken to the scene of his defeat and was there tomahawked in cold blood by Wawequa, the brother of Uncas. There is a monument to Miantonomo in Sachem's Neck, Norwich, Conn.

MIANWALLI, a town and district of India in the Multan division of the Punjab. The town is situated on the left bank of the Indus, 655 ft. above sea-level. Pop. (1901), 3,591. The district was formed in 1901, after the creation of the North-West Frontier Province, out of the Cis-Indus portions of Bannu and Dera Ismail Khan districts. Area 7816 sq. m. Pop. (1901), 423,588, showing an increase of 6-1% in the decade. About three-quarters of the district lies in the east of the Indus. Along the dry, low fertile tract, liable to floods. The remaining upland, known as the Thal, is barren and sandy, cultivable only where irrigation is possible. In the north-east the district includes the western flank of the Salt Range. The part of the district west of the Indus is a level and fairly fertile plain, enclosed by the Chichali and Maidani hills. The chief agricultural products are wheat and other grains and oil-seeds. Hides and wool are also exported, together with small quantities of alum (abundant in the Salt Range), salt (from the Salt and Maidani ranges), and coal of poor quality, which is found at several points. Petroleum has been discovered. The district is served by the Multan-Rawalpindi line of the North-Western railway.

MIAOTSE, or MIAUTSE, one of the aboriginal tribes of southern China. At one time they occupied a considerable portion of the fertile lands which now form the central province of the empire, but as the Chinese advanced southwards they were driven into the mountainous regions of the provinces of Yunnan, Kwei-chow, Kwang-si and Kwang-tung, where they are found at the present day. As early as the reign of King Suan (about 800 B.C.) we read of an expedition having been sent to drive them out of Hu-nan. The last important campaign against them was undertaken by the emperor K’ien-lung, who, having completely subjugated the Miao, attached the Mianzai, who suffered a crushing defeat, and were compelled to purchase peace by swearing allegiance to their conquerors. They still maintain a semi-independence in their mountain-homes, but are a decaying race, gradually giving way before the Chinese. They are allowed to govern themselves on their own patriarchal system. The Miao-tse of both sexes are shorter and darker-complexioned than the Chinese, their faces are rounder and their features sharper.

MIAOULIS, ANDREAS VOKOS or BOKOS (1768-1839), Greek admiral and politician, was born in Negropont. The surname Miaoulis, which was added to his family name of Vokos, or Bokos, is said to be derived from the Turkish word miaoulis, a felucca. He settled in the island of Hydra on the east of the Morea, and when the Greek War of Independence began was known among his fellow townsman as a trader in corn who had gained wealth, and who made a popular use of his money. He had been a merchant captain, and was chosen to lead the naval forces of the island. He was appointed commander-in-chief of the Greek fleet.

The islanders had enjoyed some measure of exemption from the worst excesses of the Turkish officials, but suffered severely from the conscription raised to man the Turkish ships; and though they seemed to be peculiarly open to attack by the Sultan's forces from the sea, they took an early and active part in the rising. As early as 1822 Miaoulis was appointed navarch, or admiral, of the swarm of small vessels which formed the insurgent fleet. He commanded the expedition sent to take revenge for the massacre of Chio (see Kanaris) in the same year. He continued to be the naval chief of the Greeks till Lord Dundonald entered their service in 1827, when he retired in order to leave the English officer free to act as commander. In the interval he had had the general direction of the naval side of the Greek struggle for freedom. He had a share in the successful relief of the first siege of Missolonghi in December 1822 and January 1823. In 1824, after the conquest of Psara by the Turks, he commanded the Greek forces which prevented the further progress of the Sultan's fleet, though at the cost of the loss of many fire ships and men to themselves. But in the same year he was unable to prevent the Egyptian forces from occupying Navarino, though he harassed them with some success. During 1825 he succeeded in carrying stores and reinforcements into Missolonghi, when it was besieged for the second time, though he could not avert its fall. His efforts to interrupt the sea communications of the Egyptian forces failed, owing to the enormous disproportion of
the two squadrons in the siege of the Greeks and the
ships of the war went on the naval power of the Greeks diminished, partly
owing to the poverty of their treasury, and partly to the growth of
piracy in the general anarchy of the Eastern Mediterranean.
When Miaoulis retired to make prep for Dondorrin the conduct
of the struggle had been transferred into the hands of the powers.
When Miaoulis' independence had been obtained, Miaoulis in his old age
was entangled in the civil conflicts of his country, as an opponent
of Capodistrias and the Russian party. He had to employ his
skill in the employment of fireships against them at Poros in 1831.
He was one of the deputation sent to invite King Otho to accept
the crown of Greece, and was made rear-admiral and vice-
admiral by him. He died on the 24th of June 1835 at Athens.

**MICA**, a group of widely distributed rock-forming minerals, some of which have important commercial applications. The principal members of the group are muscovite, biotite, phlogi-
pite, and lepidolite (q.v.). The name mica is probably derived from the Latin *micare*, to shine, to glitter; the German word *glimmer* has the same meaning. The mineral was probably
included with selinite under Pliny's term *lapis specularis*.

**Mineralogical Characters.**—The micas are characterized by a
very easy cleavage in a single direction and by the high degree of
flexibility, elasticity and toughness of the extremely thin cleavage
flakes. They all crystallize in the monoclinic system, often,
however, in forms closely resembling those of the rhombohedral
or orthorhombic systems. Crystals have usually the form of
hexagonal or rhomb-shaped scales, plates or prisms, with plane
angles of 60° and 120°, and, with the exception of the basal
planes, are only rarely bounded by smooth and well-defined
faces. The crystal represented in fig. 1 is bounded by the basal
pinacoid (c 001) parallel to which is the perfect cleavage, the
chlopinacoid (0 10) parallel to which is a pyramidal
pyramids m (2 11) and o (1 11). The angles between these pyra-
mids and the basal plane are 85° and 73° respectively.
The prism (110) at 90° from the basal plane is not developed as a
crystal face, but is a plane of twinning, the two individuals
of the twin being united parallel to the basal plane (fig. 2).
The different species of mica have very nearly the same forms and
interfacial angles, and they not infrequently occur intergrown
together in parallel position. The best developed crystals
are those of Vesuvian biotite.

When a cleavage flake of mica is struck a sharp blow with a
blunt needle-point a six-rayed star of cracks or */'perfusion figure*
as developed: the rays intersect at angles of approximately 60°,
and the pair most prominently developed are parallel to the
plane of symmetry of the crystal. A similar six-rayed system of
cracks, bisecting the angles between the rays of the previous set, is
produced when a blunt punch is gradually pressed against a sheet
of mica; this is known as the "pressure figure." These cracks coincide
with planes of easy separation or of gliding in the crystal; they are
especially useful in helping to determine the crystallographic orienta-
tion of a cleavage flake of mica when crystal faces are broken or
stained. Sheets of mica in which the macroscopic effects of earth-movements are
frequently cracked and ridged parallel to these directions, and are
then valueless for economic purposes.

In their optical characters the micas exhibit considerable variations,
the indices of refraction are not high, the mean index being
about 1.58-1.60, but the double refraction is very strong (0.04-0.05)
and is negative in sign. The angle between the optic axes varies
from 70°-90° in muscovite and lepidolite to 10°-15° in biotite and
phlogopite; the latter and thus frequently practically uniaxial. The
acute bisectrix of the optic axes never deviates from the normal
to the basal plane by more than a degree or two, hence a cleavage
flake of mica will always show an optic figure in convergent light
when placed at the stage of a polarizing microscope. The plane of
the optic axes may be either perpendicular or parallel to the plane
of symmetry of the crystal, and according to its position two classes
of mica are distinguished. To the first class, with the optic axial
plane perpendicular to the plane of symmetry, belong muscovite,
lepidolite, paragonite, and a rare variety of biotite called anomolite;
the second class includes zinwaldite, phlogopite, lepidolite and
most biotites. Dark coloured micas are strongly pleochroic. Ac-
curate determinations of the optical orientation, as well as the
symmetry of the etching figure on the cleavage planes, seem to
suggest that the micas, except muscovite, may be anorthic rather
than monoclinic in crystallization.

The different kinds of mica vary from perfectly colourless and
transparent to very opaque, yellow, green, red, brown, black and opaque—like in lepidolite; the
former have a pearly lustre and the latter a submetallic lustre
in the cleavage surfaces. Sheets of mica very often show
coloured rings and bands (Newton's rings), due to the interference
of light at the surfaces of internal cleavage cracks. The spec.
grav. varies between 2.7 and 3.1 in the different species. The
hardness is 2-3; smooth cleavage surfaces can be just scratched
with the finger-nail. The micas are bad conductors of heat and
electricity, and it is on these properties that many of their
technical applications depend.

Inclusions of other minerals are frequently be observed in
mica. Flattened crystals of garnet, films of quartz, and needles
of tourmaline are not uncommon. Cleavage sheets are frequently
disfigured and rendered of little value by brown, red or black spots
and stains, often with a dendritic arrangement of iron oxides.
Minute acicular inclusions, probably of rutile, arranged parallel
on the cleavage planes, give rise to the phenomenon of
anisotropism in some micaceous minerals, especially phlogopite: a candle-flame
or spot of light viewed through a cleavage sheet of such mica
appears as a six-rayed star.

**Chemical Composition.**—The micas are extremely complex
and variable in composition. They are silicates, usually ortho-
silicates, of aluminium together with alkalis (potassium, sodium,
lithium, rarely rubidium and caesium), basic hydrogen, and, in
some species magnesia, ferrous and ferric iron, rarely
chromium, manganese and barium. Fluorine is also often an essential
constituent, and titanium is sometimes present.

The composition of the several species of mica is given by the
following formulae, some of which are only approximate. It will
be found that the general formula of the micas may be given
by the expression 

\[ \text{H}_2\text{K} \text{Al}_x \text{Si}_{2-3x} \text{O}_{10}(\text{OH,F}) \]

The water which is present in muscovite to the extent of 4 to 6 %
and rather less in the other species, is expelled only at a high temper-
atures and is therefore a composition, existing as basic hydrogen
or as hydroxyl, replacing fluoride.

Rosalite is a mica in which the aluminium is largely replaced
by vanadium (V_2O_5, 30 %); it occurs as brownish-green scaly
aggregates, intimately associated with gold in California, Colorado and
Western Australia.

Various attempts have been made to explain the variations in
composition of the micas. G. Tschermak, in 1878, regarded them as
isomorphous mixtures of the following fundamental molecules:

- **H_2K Al SiO_3**
- **H_2Na Al SiO_3**
- **H_2Fe Al SiO_3**
- **H_2Fe Fe SiO_3**
- **H_2FeFe Al SiO_3**

The water which is present in muscovite to the extent of 4 to 6 %
and rather less in the other species, is expelled only at a high temper-
atures and is therefore a composition, existing as basic hydrogen
or as hydroxyl, replacing fluoride.

**Occurrence.**—Mica occurs as a primary and essential con-
stituent of igneous rocks of almost all kinds; it is also a common
product of alteration of many mineral silicates, both by weather-
ing and by contact- and dynamo-metamorphic processes. In
sedimentary rocks it occurs as detrital material.

Muscovite and biotite are commonly found in siliceous rocks,
whilst phlogopite is characteristic of calcareous rocks. The best
crystallized specimens of any mica are afforded by the small brilliant
specimens obtained from the Pyrenees, which occur as cavities in the limestone and
are ejected from Monte Somma, Vesuvius. Large sheets of muscovite,
such as are of commercial value, are found only in the very coarsely
crystallized pegmatite veins traversing granite, gneiss or mica-
schist. These veins consist of felspar, quartz and mica, often
with small amounts of other crystallized minerals, such as tourmaline,
byrnel and garnet; they are worked for mica in India, the United
States (South Dakota, Colorado and Alabama), and Brazil (Goyaz, Bahia and Minas Geraes). The commercially valuable micas of Canada and Ceylon are mainly phlogopite (q.v.), which has a rather different mode of occurrence. The mica mined in India is practically all muscovite. The principal mining districts are those of Hazaribagh in Bengal and Nellore in Madras; in the former district the mica has usually a ruby tint, whilst in the latter it is more often greenish. In the Inukituri mine, Nellore, "books" of mica measuring 5 ft. across and 15 ft. across the folia have been found, and rectangular sheets measuring 30 by 24 in. and free from cracks and flaws have frequently been obtained.

Uses.—On account of its transparency and its resistance to fire and sudden changes of temperature, mica has been much used for the windows of stoves and lanterns, for the peep-holes of furnaces, and the chimneys of lamps and gas-burners. At one time it was used for window panes of houses and the port-holes of Russian men-of-war, being commonly known as "Muscovy glass." Spangles of mica are much used for decorative purposes of various kinds, and the mineral was formerly known as glacies Mariae (Ger., Frawenglas) because of its use for decorating statues of the Virgin. The lapis specularis of Pliny, scattered over the Circus Maximus to produce a shining whiteness, was probably mica. Large quantities of ground mica are used in the manufacture of paints, and to produce a frosted effect on toys, stage scenery, &c. Powdered mica is also used in the manufacture of paints and paper, as a lubricant, and as an absorber of nitro-glycerine and disinfectants. Sheets of mica are used as a surface for painting, especially in India; for lantern slides; for carrying photographic films; as a protective covering for pictures and historical documents; for mounting soft and collapsible natural history specimens preserved in spirit; for the vanes of anemometers; mirrors of delicate physical instruments; for various optical and many other purposes. Being a bad conductor of heat it is used for the packing and jackets of boilers and steam-pipes. Other applications depend on the strength of its resistance to acids.

The most extensive application of mica at the present day is for electrical purposes. Being a bad conductor of electricity it is of value as an insulator, and the smooth flexible sheets are much used in the construction of armatures of dynamos and in other electrical machinery. For various purposes a manufactured material known as "micantie" or "micantine cloth" is much used; this consists of small sheets of mica cemented with shellac or other insulating cement on cloth or paper.

Muscovite and phlogopite are practically the only species used commercially, the former being more the mica of paper. Phlogopite is rarely found as colourless transparent sheets and is therefore almost exclusively used for electrical purposes. Many other uses of mica might be mentioned. The potassium it contains renders it of value as a manure. The species lepidolite is largely used for the manufacture of lithium and rubidium salts.

Mining, Preparation and Value.—Mica mining is an industry of considerable importance, especially in India; but here the methods of mining are very primitive and wasteful. In working downwards in open quarries and in tortuous shafts and passages much of the mica is damaged, and a large amount of labour is expended in hauling waste material to the surface. Since the mineral occurs in definite veins, a more satisfactory and economical method of working should be adopted that adopted in metalliferous mines, with a vertical shaft, cross-cuts, and levels running along the strike of the vein; the mica could then be extracted by overhead stopping, and the waste material used for filling up the worked-out excavations.

In dressing mica the "books" are split along the cleavage into sheets of the required thickness, and the sheets trimmed into rectangles with a sharp knife, shears or guillotine, stained and damaged portions being rejected. The dressed sheets are sorted according to size, transparency, colour and freedom from spots or stains. Scrap mica is ground to powder or used in the manufacture of micantine.

The price of mica varies very considerably according to the size, transparency and quality of the sheets. An average price for cut sheets of all sizes is about 4s. per lb., but for large sheets it may be as high as 54s. per lb.

MICAH (mī-kā), in the Bible, the name prefixed to the sixth in order of the books of the minor prophets. He was a contemporary and fellow-worker of Isaiah. The name in various modifications—Micahāth, Mīkāthā, Micāḥā—commonly occurs in the Old Testament, expressing as it does a fundamental point of Hebrew faith: Who is like Yahweh? It was also borne among others by the Danite whose history is given in Judges xvii. seq. (see separate article), by the prophet who opposed Ahaz's expedition to Ramoth-Gilead (1 Kings xxii.3), and by the son of Jonathan (see SAUL).

The editorial title of the book of Micah declares that Micah prophesied "in the days of Jotham (739-734), Ahaz (733-712) and Hezekiah (720-693), kings of Judah." Nothing in the book itself can claim to belong to the reign of Jotham, but the prophecy against Samaria (i. 5-9) may have been uttered originally before the fall of Samaria in 722, i.e. in the reign of Ahaz. In its present form, however, it is very likely that the prophecy against Samaria belongs most probably to the years 705-702, when a new Palestinian rising provoked Sennacherib's campaign of 707 (Nowack; cf. Marti). This prophetic activity of Micah under Hezekiah is confirmed by the direct statement of Jer. xxvi. 17 seq., where Mic. iii. 12 is quoted ("Zion shall be plowed as a field," &c.). The verse quoted forms the climax of Mic. i.-iii., from which chapters only any certain conclusions as to the prophetic message of the historic Micah can be drawn; the remaining sections of the present book (iv.-v., vi.-vii) consist, in whole or in greater part, of writings belonging to a later period.

Chs. i.-iii. (with the exception of two verses, ii. 12, 13) are a prediction of judgment on the sins of Judah and Ephraim. In the exordium Yahweh Himself is represented as coming forth in the thunderstorm (cf. Amos i. 2) from His heavenly palace, and descending on the mountains of Palestine, at once as witness against His people, and the executioner of judgment on their sins. Samaria is sentenced to destruction for idolatry; and the blow extends to Judah also, which participates in the same guilt (ch. i.). But, while Samaria is summarily dismissed, the sin of Judah is analysed at length in chs. ii. and iii., in which the prophet

1 A confusion between the two prophets of the name has led to the insertion in the Massoretic text of 1 Kings xxii. 28 of a citation from Micah i. 2, rightly absent from the LXX.

2 See, however, Gray, Hebrew Proper Names, p. 157: "In later times, Micah has hardly been part of a pious fraud, but this is not to be assumed for early times. The shorter forms may well have had a purely secular reference, signifying 'who is like this child?'"

3 He is called the Morashite (Mic. i. 1; Jer. xxvi. 18) from Hazor-Athpole, Moresheth-Gath. That Micah lived in the Shephelah or Judaean lowland near the Philistine country is clear from the local colouring of i. 10 seq., where a number of places in this quarter are mentioned together (in connexion with the war in Philistia), and their names play a part that they do not play in any other region, suggesting ties of close affinity but a division of the district. The paronomasia makes the verses difficult, and in i. 14 none of the ancient versions recognizes Moreshesh-Gath as a proper name. The word Morashite (Morashith) was therefore obscure to them; but the fact of giving greater weight to the second syllable, with the in the first syllable, which is as old as the LXX., and goes against the view, taken by the Targum both on Micah and on Jeremiah, and followed by some moderns (including Cheyne, E.B., 3198), that Micah came from Moresheth, the "merciless town," near Gath. When it is realized that this is not likely he is thinking of Moreshah (Marae), for he speaks of the former as a village and of the latter as a ruin, 2 m. from Eleutheropolis. Jerome too in the Epi. Pseud. (Ep. xxv.)Speaking of a village of the name belonging to the church of Micah's sepulchre, from Marea. This indeed was after the pretended miraculous discovery of the relics of Micah in A.D. 355; but the name of the village which then existed (Præf. in Mic.) can hardly have been part of a pious fraud.

4 These verses are a prophecy of restoration; they are admitted an interruption in their present context (so, e.g., Driver, G. A. Smith); they belong in substance to the second section of the book (iv. v.).
no longer deals with idolatry, but with the corruption of society, and particularly of its leaders—the grasping aristocracy whose whole energies are concentrated on devouring the poor and depriving them of their little holdings, the unjust judges and priests who go in for the common practices of the hireling prophets. The hireling prophets make war against everyone one "that putteth not into their mouth," but are ever ready with assurances of Yahweh's favour to their patrons, the wealthy and noble sinners that fatten on the sweat of the poor. The hireling prophets who are denounced by Micah are also prominent in Isaiah's prophecies; they were closely connected, not only with the foreign complications due to the approach of the Assyrians, but with the break-up of the old agrarian system within Israel, and with the rapid and uncom- pen sated process of development among the Chaldeans and Babylonians following the years when the conquest of Edom by Amaziah and the occupation of the port of Elath by his son (2 Kings xiv. 7, 22) placed the lucrative trade between the Mediterranean and the Red Sea in the hands of the greater powers. Thus the departure of the Assyrians to the east and the invasion of the north by the Medes and Persians, which distinguishes Micah from Isaiah, and his announcement of the impending fall of the capital (the deliverance of which from the Assyrian appears to Isaiah as the necessary condition for the preservation of the seed of a new and better kingdom), are plainly the fact that, while Isaiah lived in the centre of affairs, Micah, a provincial prophet, sees the capital and the aristocracy entirely from the side of a man of the oppressed people, and fore-tells the extermination of the greater oppressors of Israel. But this ruin does not present itself to him without the involving the ruin of the nation as a whole; the congregation of Yahweh remains in Judaea when the oppressors are cast out (ii. 5); Yahweh's words are still good to them that walk uprightly; the glory of the glory will still rest upon the houses of Judah and Jerusalem, as when David's band of broken men was the true hope of the nation, but there is no hint that it is banished from the land.1

Our only evidence as to the reception of Micah's message by his contemporaries is that afforded by Jer. xxvi. 17 seq., both directly, in the recorded effect on Hezekiah and the people; and indirectly, in the fact that the impression created was remembered a century afterwards. Micah resembles Amos both in his country origin and in his general character, which expresses itself in strong emphasis on the ethical side of religion. As the last of the four great prophets of the 8th century he undoubtedly contributed to that religious and ethical reformation whose literary monument is the Book of Deuteronomy.2

The remainder of the book bearing the name of Micah falls into two main divisions, viz. iv., v. and vi., vii. Each differs from the first division (i.–iii.) in a marked degree. The second consists mainly of prophecies of restoration including eschatological (iv. 1 seq.) and Messianic (v. 2 seq.) hopes. The third is formed of three or four apparently unrelated passages, on the spirituality of true worship (vi. 1–8), social immorality and its doom (vi. 9–16; vii. 1–6) and Israel's future recovery from present adversity through Divine grace (vii. 7–20). It is improbable that much, if any, of these chapters can be ascribed to Micah himself,3 not only because their contents are so different from his undoubted work (i.–iii.), for which he was subsequently remembered (Jer. xxvi. 18), but because the historical outlook of the writing is of a later age (e.g. iv. 6 seq.; vii. 7 seq.). It is neither psychologically nor historically impossible for a prophet of the 8th century to write of the 7th century B.C. The reason making this view the more probable one is given by Wellhausen (p. 281), who prefers to regard the book as a collection made up of various fragments of the same prophet's works and having justly crystallized around two central passages, viz. iv. 1–4, and vi. 6–8, whose addition to the first three chapters formed the second stage in the growth of the present book. More conservative views as to authorship are taken by Driver and G. A. Smith, the former suggesting, however, that the existing Book of Micah consists only of a collection of excerpts, in some cases fragmentary excerpts, from the entire series of the prophet's "discourses" (L. O. T., ch. vi. § 6).

judgment to be also a prophet of comfort; but the internal evidence of composite and (in whole or part) later authorship must outweigh the traditional attachment of these passages to a MS. containing the work of Micah.

The sequence of thought in chs. iv., v. is really difficult, and has given rise to much complicated discussion. Thus iv. 11–13 stands in direct contradiction to iv. 9, 10, and indeed to iii. 12. The last two passages agree in speaking of the capture of Jerusalem, the first declares Zion inviolable, and its capture an impossible anathema. Such a position can be reconciled to the more general fact of the violent and harmonistic process of imagining that two quite distinct positions, separated by a renewal of the theocracy, are spoken of in consecutive verses. Another difficulty lies in the words "the house of Asher..." etc. It seems that Micah unquestionably looked for the destruction of Jerusalem as well as of Samaria in the near future and by the Assyrians (i. 9, and this was the judgment which Hezekiah's repentance avowed. If these words, therefore, belong to the original context, they may well be from Micah's hand; though they might be a later gloss. The prophetic thought is that the daughter (population) of Zion shall not be saved by her present rulers or defensive strength; she must be saved from her bulwarks and dwell in the open field; there, and not within her city, shall Yahweh "raining upon" her from her enemies. Opposition to present tyranny expresses itself in recurrence to the old popular ideal of the first simple Davidic kingdom (iv. 8). These old days shall return once more. A new David shall arise and to him shall be given the "throne..." of David (iv. 8, 2). These visions, like the conception of Solomon, the strongholds, the fortified cities, the chariots and horses so foreign to the life of ancient Israel, are no more known; they disappear together with the divinations, the soothsayers, the idolatry, the Asherah and the Yahweh of the high places. Yahweh is king on Mount Zion, and no inventions of man come between Him and His people.

The sixth chapter of Micah presents a very different situation from that of the chapters that have preceded it. From chs. i.–iv. Micah speaks with his people for their sins, but the sinners are no longer a careless and oppressive aristocracy buoyed up by deceptive assurances of Yahweh's help, by prophecies of wine and strong drink: they are bowed down by a religion of terror, wearied with attempts to propitiate an angry God, ravaged by foreign enemies, and even the sacrifice of the first-born. Meantime the substance of true religion—justice, charity and a humble walk with God—is forgotten, fraud and deceit reign in all classes, the works of the house of Ahab are multiplied against the land, and the issue can be nothing else than its total desolation. All these marks may be held to fit exactly the evil times of Manasseh as described in 2 Kings xxvi. Cp. vii. 3, 4, "At the beginning of Manasseh's reign the land had sinned against its Maker..." Micah does not say that the people's desolate age is bitterly bewailed, possibly belongs to the same context.

Micah may very well have lived into Manasseh's reign, but the title in i. 1 does not cover a prophecy which certainly falls after Hezekiah's death, and the style has nothing in common with the earlier part of the book. It is therefore prudent to regard the prophecy, with Ewald, as anonymous. Ewald ascribed the whole of chs. vi., vii. to one author. Wellhausen, however, remarks with justice that the thread is abruptly broken at vii. 6, and that verses 7–20 represent (i.e. xxxix.; xl.-lv. lvi.-lvi.) in the character of the three divisions (judgment; coming restoration; prayer for help in adversity) respectively, and in the fact that the first alone gives us pre-exilic writing in the actual words of the prophet to whom the whole book is ascribed. In both cases, it need hardly be said, the great literary and spiritual value of the later passages ought to be in no way neglected.

1 See the Introduction to the Century Bible, "Deuteronomy and Joshua," by H. Wheeler Robinson.
2 Mic. iv. 1–3 and Isa. ii. 2–4 are but slightly modified recensions of the same speech (cf. Driver). Mic. iv. 4 is a later hand than the prophecy of Micah, while on the other hand Mic. iv. 4 seems the natural completion of the passage, it is common to suppose that both copy one older prophet. But the prophet has little connexion with the context in language, and may be the quotation of a copyist suggested by v. 5. On the other hand it has been urged that the passage belongs to a later stage of prophetic thought than the 8th century B.C. Reasons making this view the more probable one are given by Wellhausen (p. 281).
3 Nowack thinks that iv. 9, 10, 14 and v. 10–14 may possibly belong to Micah: Wellhausen recognizes the same possibility, which he extends, however, to vi. 1–8. Marti, who (like Cheyne in Exodus) finds the speech of Mic. iv. 5–8 by Mic. iv. 4, has crystallized round two central passages, viz. iv. 1–4, and vi. 6–8, whose addition to the first three chapters formed the second stage in the growth of the present book. More conservative views as to authorship are taken by Driver and G. A. Smith, the former suggesting, however, that the existing Book of Micah consists only of a collection of excerpts, in some cases fragmentary excerpts, from the entire series of the prophet's "discourses" (L. O. T., ch. vi. § 6).

1 Regarded by Stade (Z. T. W., 1903, p. 164 seq.) as an independent psalm.
to suffer prejudice from critical conditions as to their date and authorship.

LITERATURE.—The chief modern commentators are those of Nowack (Die Kleinen Propheten, 1897; 2nd ed., 1904) and Marti (Dodekaphrornheten, 1904), where detailed references to the older literature may be found; cf. Wellhausen, Die Kleinen Propheten (3rd ed., 1898). In English, reference may be made to Cheyne ("Micah," in the Bible, S.D., ii. 324-329; also "The Book of the Twelve," vol. i., in The Expositor's Bible, 1896); also to the articles on "Micah" by Nowack in Hastings's Dict. of the Bible (1900), iii. 359, 360, and by Cheyne in the Ency. Bibl. (1902), iii. c. 3068-3074. The article of the original articles (Ency. Bibl. and Brit. Ency., 4th ed.) by W. Robertson Smith, which has been revised above. For a recent review see Cheyne, introduction to W. R. Smith's The Prophet's of Isrul, 2nd ed., pp. xxiii.-xxiv.; also Ency. Bibl. loc. cit. J. M. F. Smith discusses the water foundation of the Prophet's in a volume of Old Test. and Semitic Studies: in memory of W. R. Harper (Chicago, 1908).

MICAH, in the Bible, a man of the hill-country of Ephraim whose history enters into that of the foundation of the Israelite sanctuary at Dan (Judges xvii. seq.). He had stolen from his mother eleven hundred pieces of silver (for the number cf. Judges xvi. 5), and when she uttered a curse upon the unknown thief he restored the money and she consecrated it to Yahweh. A carved image was made and set up in his private temple with an ephod-idol and teraphim (objects used in divination, cf. Gen. xxi. 19, 30; Hos. iii. 4). He employed one of his sons to serve as priest, but when a Levite from Bethel in Judah came along he gladly installed him as "father and priest" in the rival town of Dan. Customary enough was this or this and others has been passed along to its new home and territory and sent men to search for a suitable district they passed by Micah's house, recognized the Levite and requested an oracle from him. When, later, they migrated, they despoiled the sacred place and carried off the gods and priest to their newly won home at Laish.

MICA-SCHISTS, in petrology, a rock composed essentially of mica and quartz, and containing a thin parallel-banded or foliated structure, with lamellae rich in mica alternating with others which are principally quartz. They split readily along the micaceous films, and have smooth or slightly uneven surfaces covered with lustrous plates of muscovite or biotite; the quartzose lamellae are often visible only when the specimens are looked at edgewise. Mica-schists are very common in regions of Archean rocks accompanying gneisses, crystalline limestones and other schists. Some have a flat banding yielding smooth slabs; others are crumpled or contorted with undulating foliation. Occasionally the quartz forms elongated lenticles or "eyes." In some cases mica composes nearly the whole of the rock, in others quartz preponderates so that they approach quartz-schists and quartzites.

The mica may be muscovite or biotite; both are often present, while paragonite and green fuchsite or chrome-mica are not so common. In addition to quartz there may be a small amount of feldspar, usually albite. A great number of accessory minerals are known in mica-schists, and when these are conspicuous or important they may be regarded as constituting special varieties receiving distinctive names. Garnet, in rounded red crystals, not uncommonly idiomorphic, is the most frequent. Brown staurolite, pinkish andalusite, and grey or blue kyanite occur in some kinds of mica-schists. These andalusites are the varieties of the leucite of the Goarth contains kyanite and staurolite. Graphite (graphophyt), which is also a very frequent ingredient of these rocks, giving them a leaden grey colour and causing them to soil the fingers when handled. In some mica-schists there is much calcite (calc-mica-schists); and hornblende, scapolite and augite are often seen in rocks of this sort. Tourmaline occurs, sometimes in large black prisms, but more commonly in minute crystals visible only in microscopic sections. Rutile, magnetite and hematite are also frequent inclusions. Phlogopite, zircon, apatite, granules of epidote or zoisite chlorite, chloritoid and pyrites occur with more or less frequency in the rocks of this group.

Mica-schists are in nearly all cases sedimentary rocks which have been subjected to the processes of deformation and recrystallization, and are thus of metamorphic origin. The association of quartzites and quartz-schists, graphite-schists and crystalline limestones with mica-schists in the field is explained by the fact that all these rocks are altered sediments, viz., sandstones, carbonaceous shales and limestones.

Under the microscope the appearance presented by mica-schists differs according to whether the rock is cut parallel to or across the planes of foliation. In the latter case thin alternating bands composed of black or brown mica, and of quartz, cross the field of view (see Petrology, Plate 4, fig. 8). The mica scales have their cleavages and their flat sides parallel to the foliation or rounded, elliptical or irregular grains, with usually a small admixture of feldspar (albite, oligoclase, orthoclase);apatite and iron oxides are rarely absent from these rocks. If garnet is present it may form large well-shaped crystals, or it may break, without appearing; it is rounded, elliptical, or irregular, with commonly a small ad-
MICHAEL (1596–1645), tsar of Russia, was the first tsar of the house of Romanov, being the son of Theodore Nektich Romanov, afterwards the Patriarch Philipet (q.v.), and Xenia Chestovaya, afterwards the nun Martha. He was elected unanimously tsar of Russia by a national assembly on the 21st of February 1613, but not till the 24th of March did the delegates of the council discover the young tsar and his mother at the Ipatievsky monastery near Kostroma. At first Martha protested that her son was too young and tender for so difficult an office in such troublesome times. At the last moment, however, Michael consented to accept the throne, but not till the weeping boyars had solemnly declared that if he persisted in his refusal they would hold him responsible to God for the utter destruction of Muscovy. In so dilapidated a condition was the capital at this time that Michael had to wait for several weeks at the Troitsa monastery, 75 m. off, before decent accommodation could be provided for him at Moscow. He was crowned on the 22nd of July. The first care of the new tsar was to clear the land of the robbers that infested it. Sweden and Poland were then got rid of respectively by the peace of Stoilova (March 10, 1617) and the truce of Deuila (Feb. 13, 1619).

The most important result of the truce of Deuila was the return from the French frontier of the tsar's sister, who henceforth took charge of the government till his death in October 1633, Michael occupying quite a subordinate position. He was a gentle and pious prince who gave little trouble to any one and effaced himself behind his counsellors. Fortunately for him they were relatively honest and capable men. Michael's failure to wed his daughter Irene with Prince Waldemar of Denmark, in consequence of the refusal of the latter to accept orthodoxy, so deeply afflicted him as to contribute to bring about his death on the 12th of July 1645.

Sec R. Nisbet Bain, The First Romanovs (Lond., 1905). (R. N. B.)

MICHAEL, the name of nine East-Roman emperors. Michael II. Rhangabes (d. 845), an obscure nobleman who had married Procopia, the daughter of Nicephorus I., and been made master of the palace. He was made emperor in a revolution against his brother-in-law, Stauracius (811).

Theodora, born 812 or 813, was the daughter of Emperor Michael I. She was married to an officer named Isaac Connenus, who died in 837. Theodora then married a slave, Leo. When they were living together, Michael II. succeeded to the throne, and Theodora became empress (842). In 843, Michael II. was deposed and killed by the army. Theodora reigned as empress regent for her son, Michael III. (843–858). She was succeeded by her son Michael III. (858–867), who was deposed and murdered in 867 by his minister Bardas, who was appointed emperor in his stead (867–871). Michael III. was succeeded by his son Michael IV. (871–886), who was deposed and murdered in 886 by his minister Bardas, who was appointed emperor in his stead (867–871).

Michael IV. (d. 1041), being a weak character and subject to epileptic fits, left the government in the hands of his brother, John the Eunuch, who had been first minister of Constantine and Romanus. John's reforms of the army and administration failed, and the strength of the Empire, which held its own successfully against foreign enemies, was weakened. On the eastern frontier the important post of Edessa was relieved after a prolonged siege. The western Saracens were almost driven out of Sicily by George Maniakes (1038–40), but an expedition against the Italian Normans suffered several defeats, and after the recall of Maniakes most of the Sicilian conquests were lost (1041). In the north the Serbs achieved a successful revolt (1040), but a dangerous rising by the Bulgarians and Slavs threatened the cities of Thrace and Macedonia, which was repressed by a triumphant campaign which induced Michael to retire from the throne (1041).

Michael V. Calaphates, or "the caulkier," nephew and successor of the preceding, surnamed after the early occupation of his father. He owed his elevation (Dec. 1041) to his uncle John, whom along with Zoe he almost immediately banished, this led to a popular tumult in consequence of which he was dethroned after a brief reign of four months, and relegated to a monastery. His unpopularity seems largely due to his attempts at administrative reform, which were strongly resented by the dominant classes.

Michael VI. was already an old man when chosen by the empress Theodora as her successor shortly before her death in 1056. He was unable to check the disaffection of the feudal aristocracy, who combined with an officer named Isaac Connenus to depose him. After a successful battle in Phrygia, the rebels had no difficulty in dethroning Michael (1057), who spent the rest of his life in a monastery.

Michael VII. Ducas, or Parapinaces, was the eldest son of Constantine X. Ducas. After a joint reign with his brothers, Andronicus I. and Constantine XI. (1067–1071), he was made sole emperor through his uncle John Ducas. The feebleness of Michael, whose chief interest lay in trifling academic pursuits, and the avarice of his ministers, was disastrous to the empire. As the result of anarchy in the army, the Byzantines lost their last possessions in Italy (1071), and were forced to cede a large strip of Asia Minor which they were unable to defend against the Seljuk Turks (1074). These misfortunes, which were but partially repaired by the suppression of the Bulgarian revolt (1079), caused widespread dissatisfaction. In 1079 two generals, Nicephorus Bryennius and Nicephorus Botanites, simultaneously revolted. Michael resigned the throne with hardly a struggle and retired into a monastery. His nickname Parapinaces ("starver") was due to his causing the price of wheat to rise.

Michael VIII. Palaeologus (1234–1282) was the son of Andronicus Palaeologus Connenus and Irene Angela, the granddaughter of Alexius Angelus, emperor of Constantinople. At an early age he rose to distinction, and ultimately became...
commander of the French mercenaries in the employment of the emperors of Nicea. A few days after the death of Theodore Lascaris II, in 1259, Michael, by the assassination of Muzalon (which he is believed but not proved to have encouraged) became joint guardian with the patriarch Arsenius of the young emperor, John Lascaris, then a lad of eight years. Afterwards invested with the title of "despot," he was finally proclaimed joint-emperor and crowned alone at Nicea on the 1st of January 1260. In July 1261 Michael, who had attacked Constantinople with the help of the Genoese, conquered the town through his general Stratempoulos. He thereupon had John Lascaris blinded and banished. For this last act he was excommunicated by Arsenius, and the ban was not removed until six years afterwards (1268) on the accession of a new patriarch. In 1263 and 1264 respectively, Michael, with the help of Urban IV., concluded peace with Villehardouin, prince of Achaja, and Michael, despot of Epirus, who had previously been invited by the pope to attack him, but had been decisively beaten at Pelagonia in Thessaly (1259); Villehardouin was obliged to cede Mistra, Monemvasia and Maina in the Morea. Subsequently Michael was involved in wars with the Genoese and Venetians, whose influence in Constantinople he sought to diminish by maintaining the balance of strength between them. In 1268 Charles of Anjou, by joint intrigue with the alleged purpose of restoring Baldwin to the throne of Constantinople, and pressed Michael so hard that he consented to send deputies to the council of Lyons (1274) and there accept the papal supremacy. The union thus brought about between the two Churches was, however, extremely distasteful to the Greeks, and the persecution of his "schismatic" subjects to which the emperor was compelled to resort weakened his power so much that Martin IV. was tempted to enter into alliance with Charles of Anjou and the Venetians for the purpose of reconquering Constantinople. The invasion, however, failed, and Michael so far had his revenge in the "Sicilian Vespers," which he helped to bring about. He died in Thrace in December 1282. In reconstituting the Byzantine Empire Michael restored the old administration without embouravouring to correct its abuses. By debasing the coinage he hastened the decay of Byzantine commerce.

Michael IX. Palaeologus, was the son of Andronicus II. and was associated with him on the throne from 1295, but ruled alone. He took the field against the Turks (1301, 1310) and against the Grand Catalan Company (1305), but was repeatedly defeated.

See Gibbon's Decline and Fall (ed. Bury, 1896); G. Finlay, Hist. of Greece (ed. 1877); G. Schlumberger, "L'Empire byzantin" (1866); J. Bury, in Eng. Hist. Rev. (1886); Mellarakes, Ιστορία του βασιλείου της Νικαιας και του δικαίου της Ιπερος, pp. 539-627 (Athens, 1898).

MICHAEL OBRENOVICH III. (1823-1868), Prince of Servia, was the youngest son of Prince Milosh, the founder of the Obrenovich dynasty. After the abdication of his father (1839) and the death of his elder brother Milan Obrenovich II. (1840) he ascended the throne of Servia. He wished to continue the work of his father, in liberating all the Servian people, and if possible all other Balkan Christians, from direct Turkish rule. But while this programme made the Sultan hostile, it also failed to win the support of Austria, which did not wish the Eastern Question to be opened by the ambitions of Servia. The suppression by which his aspirations found in Russia increased Turkey's and Austria's suspicions of the prince's activity. At the same time the political situation at home was not favourable to his anti-Turkish policy. The power was in the hands of men who had forced Obrenovich I. to abdicate, and feared that Obrenovich III. might avenge his father. They thought it safer for them to replace him on the throne by a man who was not an Obrenovich, and who would be personally obliged to them for his elevation. These motives were at the bottom of the revolt, started and led by Vuchich in August 1842, the outcome of which was that Prince Michael left the country and that his equerry, Alexander Karageorgevich, was elected Prince of Servia. As an exile Prince Michael lived principally in Vienna, improving his education by studies and travels, and frequently visiting England. He constantly refused to agree to suggestions for his restoration by forcible means. His device was Tempus et meum judiis, "Time and my right." He supported Servian authors and artists, and wrote himself a book in defence of his father Milosh against the attacks of Cyprian Robert. He wrote poetry too, and some of his songs, set to beautiful music, were very popular amongst the Servians. He married in 1856 the beautiful Julia, Countess Hunyadi.

In 1858 the Servians, having dethroned Prince Karageorgevich, recalled Michael's father Milosh Obrenovich I. Michael returned to Servia, and on his father's death (1866) ascended the Servian throne for the second time. His proclamation "that henceforth the law is the highest will in Servia," opened a new era of strict legality and at the same time of entire emancipation from foreign influences, and more especially from Turkey's interference with the internal affairs of Servia. The old constitution, granted to Servia by the sultan as the suzerain and the tsar as the protector of Servia as far back as 1839, was discarded and replaced by one which limited the power of the oligarchic senate and gave a certain share in legislation to the "Narodna Skupstina." (1864). This abolished the servile national army and increased the regular army. Reforms in all branches of public administration were introduced, and Servia, until then a half-oriental and half-patriarchal state, was resolutely led to become a civilized country in a European sense. When in 1862 the Turkish garrison bombarded the town of Belgrade from its citadel, Prince Michael, supported by the European diplomacy, succeeded in obtaining evacuation of some of the smaller forts in Servia, but the strong fortress of Belgrade still remained garrisoned by the Turkish troops. Prince Michael now made vigorous political and military preparations for war against Turkey. He made secret arrangements with the Bulgarian, Bosnian and Albanian leaders, an alliance with Montenegro and an understanding with Greece, with the object that they all should rise if Servia declared war on Turkey. He even succeeded in obtaining Austria's promise, that it would observe an attitude of friendly neutrality and would have nothing against an eventual annexation of the largest part of Bosnia to Servia, and he secured to himself the sympathies of Napoleon III. and Tsar Alexander. In the beginning of 1867 he formally asked the Porte to withdraw the Turkish garrisons from the fortress of Belgrade, as well as from other two fortresses of minor importance (Shabats and Smederevo (Semendria)). For some time the chances were that a war would take place that spring (1867) between Servia and Turkey, but peace was kept by the action of Great Britain, who advised the sultan to withdraw the Turkish garrisons from the Servian fortresses; and this advice, backed by Russia, France and Austria, prevailed at last with the sultan. On the 26th of April 1867 the fortresses were delivered over to Prince Michael, who shortly afterwards went to Constantinople to thank the sultan personally.

Prince Michael's policy had triumphed. But his success was short-lived. A group of young men, mostly educated in France and Germany, now started a liberal movement under the leadership of Yovan Ristic (or Ristitch). They wanted a more liberal constitution than that which Prince Michael had given; and this movement tended to qualify his popularity. Meanwhile the prince contemplated divorce from his wife Princess Julia, by whom he had no children, and his marriage with the daughter of his cousin Madame Anka Constantinovich; and the adherents of the exiled Karageorgevich dynasty were alarmed at the prospect of his eventually having legal heirs to the throne. A former private secretary to Prince Alexander Karageorgevich, and two of the same prince's brothers-in-law, formed a conspiracy, which resulted in the brutal assassination of Prince Michael on the 29th of May (June 10 (O.S.), 1868), whilst he was walking in the park of Koshtunya, a few miles distant from Belgrade.

MICHAELIS, JOHANN DAVID (1717-1791), German biblical scholar and teacher, a member of a family which had the chief part in maintaining that solid discipline in Hebrew and the
cognate languages which distinguished the university of Halle in the period of Pietism. Johann Heinrich Michaelis (1668-1758) was the chief director of the R. Franck's Collegium orientale theologum, a practical school of biblical and oriental philology then quite unique, and the author of an annotated Hebrew Bible and various exegetical works of reputation, especially the *Adnotationes ubiores in hagioraphos* (1729). In his chief publications J. H. Michaelis had as fellow-worker his sister's son Christian Benedikt Michaelis (1680-1764), the father of Johann David, who was likewise influential as professor at Halle, and a sound scholar, especially in Syria. J. D. Michaelis was trained for academical life under his father's eye. At Halle he was influenced, especially in philosophy, by Sigismund J. Baumgarten (1700-1762), the link between the old Pietism and J. S. Semler, while he cultivated his strong taste for history under Chancellor Ludwig. In 1739-1740 he qualified as university lecturer. One of his dissertations was a defence of the antiquity and divine authority of the vowel-points in Hebrew. His scholarship still moved in the old traditional lines, and he was also much exercised by religious scruples, the conflict of an independent mind with that submission to authority at the expense of reason encouraged by the Lutheranism, in which he had been trained. He went to England in 1741-1742 and lifted him out of the narrow groove of his earlier education. In passing through Holland he made the acquaintance of Albert Schultens (1686-1750), whose influence on his philological views became all-powerful a few years later. At Halle Michaelis felt himself out of place, and in 1745 he gladly accepted an invitation to Göttingen as privatdozent. In 1746 he became professor extramarius, in 1750 ordinarius, and in Göttingen he remained till his death in 1791.

His intellect was active in many directions; universal learning indeed was perhaps one of his foibles. Literature—modern as well as ancient—occupied his attention; one of his works was a translation of four parts of *Clarissa*; and translations of some of the then current English paraphrases on biblical books manifested his sympathy with a school which, if not very learned, attracted him by its freer air. His oriental studies were reshaped by diligent perusal of the works of Schultens; for the Halle school, with all its learning, had no conception of the principles on which a fruitful connection between Biblical and Oriental learning could be established. His linguistic work indeed was always hampered by the lack of manuscript material, which is felt in his philological writings, *e.g.* in his valuable *Supplementa* to the *Hebrew lexicon* (1784-1792). 1 He could not become such an Arabist as J. J. Reiske (1716-1774); and, though for many years the most famous teacher of Semitic languages in Europe, he had little of the higher philological faculty, and neither his grammatical nor his critical work has left a permanent mark, with the exception perhaps of his text-critical studies on the Peshitta. 2 His tastes were all for such studies as history, antiquities, and especially geography and natural science. He had in fact started his university course as a *medicinae cultor*, and in his autobiography he half regrets that he did not choose the medical profession. In geography he found a field hardly touched since Samuel Bochart, in whose footsteps he followed in the *Spicilegium geographiae hebraearum exterar post Bochartum* (1760-1780); and to his impulse we owe the famous Eastern expedition conducted by Caspar Niebuhr. In spite of his doctrinal writings—which at the time made little noise, so that his *Compendium of Dogmatic* (1760) was confiscated in Sweden, and the knighthood of the North Star was afterwards given him in reparation—it was the natural side of the Bible that really attracted him, and no man did more to introduce the modern method of studying Hebrew antiquity as an integral part of ancient Eastern life.

The personal character of Michaelis can be read between the lines of his autobiography with the aid of the other materials collected by J. M. Hassencamp (1743-1797) the editor (J. D. Michaelis Lebensbeschreibung, &c., 1793). The same volume contains a full list of his works. Besides those already mentioned it is sufficient to refer to his *New Testament Introduction* (the first edition, 1769, preceded the full development of his powers, and is a very different book from the later editions), his reprint of Robert Lowth's *Prolegomena* with important additions (1758-1762), his German translation of *Praelectiones* with additions in the Fabritius Bibliothek (1775-1785) and New O. and E. Bibl. (1786-1791), his Mosaisches Recht (1770-1771) and his edition of E. Castle's Lexicon syriacum (1785-1788). His *Literarischer Briefwechsel* (1794-1796) contains much that is interesting for the history of learning in his time.

**MICHAUD—MICHAUX**

MICHAUD, JOSEPH FRANÇOIS (1767-1839), French historian and publicist, was born of an old family on the 10th of June 1767, at Alençon, Savoy, was educated at Bourg-en-Bresse, and afterwards engaged in literary work in Paris, where the events of 1789 first called out the strong dislike to revolutionary principles which manifested itself throughout the rest of his life. In 1791 he went to Paris, where, not without danger, he took part in editing several royalist journals. In 1796 he became editor of *La Quotidienne*, for his connexion with which he was arrested after the 13th of Vendémiaire; he succeeded in escaping his captors, but was sentenced to death *par contumace* by the military council. Having resigned the editorship of his newspaper on the establishment of the Directory, he was again proscribed on the 18th of Fructidor, but at the close of two years returned to Paris where his responsibilities had superseded the Directory. His Bourbon sympathies led to a brief imprisonment in 1800, and on his release he for the time abandoned journalism, and began to write or edit books. Along with his brother and two colleagues he published in 1806 a *Biographie moderne, ou dictionnaire des hommes qui se sont fait remarquer* (32 vols., 1836-1844). The *Histoire* of Michaelis and also the first volume of his *Biographie universelle*. In 1814 he resumed the editorship of *La Quotidienne*, and in the same year was elected Academician. In 1815 his brochure entitled *Histoire des guerres successives ou le dernier règne de Bonaparte* met with extraordinary success, passing through twenty-seven editions within a very short time. His political services were now rewarded with the cross of an officer in the Legion of Honour and the modest post of king's reader, of which last he was deprived in 1827 for having opposed Peyronnet's "Loi d'Amour" against the freedom of the Press. In 1830-1831 he travelled in Syria and Egypt for the purpose of collecting additional materials for his *Histoire des croisades*; his correspondence with a fellow explorer, J. J. F. Poujoulat, consisting practically of discussions and eluciations of various points in that work, was afterwards published (Correspondance d'orient, 7 vols., 1833-1835). Like the *Histoire*, it is more interesting than exact. The *Histoire des croisades*, in four volumes more, contained the "Pieces justificateles" of the *Histoire*. Michaelis died on the 30th of September 1839, at Passy, where his home had been since 1832.

His *Histoire des croisades* was published in its final form in six volumes in 1840 under the editorship of his friend Poujoulat (9th ed., with appendix, by Huillard-Bréholles, 1856). Michaelis, along with Poujoulat, also edited *Newelle collection des mémoires pour servir à l'Histoire de France* (32 vols., 1836-1844). See *Sainte-Beuve*, *Cassiers du lundi* (vol. 7).

**MICHuids, ANDRÉ** (1746-1802), French botanist and traveller, was born at Versailles on the 7th of March 1746. In 1764 he went to the botanical garden in England, and in 1780 he explored the Pyrénées and the Alps. In 1782 he was sent by the French government on a botanical mission to Persia. His journey began unfavourably, as he was robbed by Arabs of all his equipment except his books; but he gained influential support in Persia, having cured the shah of a dangerous illness. After two years he returned to France with a fine herbarium, and also introduced numerous Eastern plants into the botanical gardens of France. In 1785 he was sent by the French government to North America, and travelled with his son François André (1770-1855) through Canada,

---

1 By a strange fortune of war it was the occupation of Göttingen by the French in the Seven Years' War, and the friendly relations he formed with the officers, that procured him the Paris MS, from which he edited Abulfeda's description of Egypt.

2 *Curse in actus apostolorum syracus* (1755).
Nova Scotia and the United States. On his return to France in 1797 he was shipwrecked and lost most of his collections. In 1800 he went to Madagascar to investigate the flora of that island, and died there on the 16th of November 1802. His work as a botanist was chiefly done in the field, and he added largely to what was previously known of the botany of the East and America.

MICHEL, CLAude, known as Clodion (1738–1814), French sculptor, was born on the 20th of December 1738 in Nancy. Here and probably in Lille he spent the earlier years of his life. In 1755 he came to Paris and entered the workshop of Lambert Sigisbert Adam, his maternal uncle, a clever sculptor. He remained four years in this workshop, and on the death of his uncle became a pupil of J. B. Pigalle. In 1759 he obtained the grand prize for sculpture at the Académie Royale; in 1761 he obtained the first silver medal for studies from models; and in 1762 he went to Rome. Here his activity was considerable between 1767 and 1771. Catherine II. was eager to secure his presence in St. Petersburg, but he returned to Paris. Among his patrons, which were very numerous, were the chapter of Rouen, the states of Languedoc, and the Directoire. His works were frequently exhibited at the Salon. In 1782 he married Catherine Flore, a daughter of the sculptor Augustin Pajou, who subsequently obtained a divorce from him. The agitation caused by the Revolution drove Clodion in 1792 to Nancy, where he remained until 1798, his energies being spent in the decoration of houses. Among Clodion's works are a statue of Montesquieu, a "Dying Cleopatra," and a chimney-piece at present in the South Kensington Museum. One of his last groups represents Homer as a beggar being driven away by fishermen (1810). On the 29th of March 1814 Clodion died in Paris, on the eve of the invasion of Paris by the allies.

Thirion's Les Adan et Clodion (Paris, 1885) contains a list of the sculpture’s works sold between 1767 and 1884. See also A. Jacquot, Les Adan et les Michel et Clodion (Paris, 1894).

MICHEL-CLEMENCE LOUISE (1830–1905), French anarchist, called La Vierge noire de Montmartre, was born at the château de Vroissant (Haute-Marne) on the 29th of May 1830, the daughter of a serving-maid, Marianne Michel, and the son of the house, Étienne Charles Demais. She was brought up by her father's parents, and received a liberal education. After her grandfather's death in 1850 she was trained to teach, but her refusal to acknowledge Napoleon III. prevented her from serving in a state school. She found her way in 1866 to a school in the Montmartre quarter of Paris, where she threw herself ardently into works of charity and revolutionary politics. She became violently anti-Bonapartist, and is said to have meditated the assassination of Napoleon. During the siege of Paris she joined the ambulance service, and untringly preached resistance to the Prussians. On the establishment of the Commune she joined the National Guard. She offered to shoot Thiers, and suggested the destruction of Paris by way of vengeance for its surrender. She was with the Communards who made their last stand in the cemetery of Montmartre, and was closely allied with Théodore Ferré, who was executed in November 1871. This ardent attachment was perhaps one of the sources of the exile which marked her career, and gave many handles to her enemies. When she was brought before the 6th council of war in December 1871 she defied her judges and defended the Commune. She was sent as a convict to New Caledonia, among her companions being Henri Rochefort, who remained her friend till the day of her death. The amnesty of 1880 found her revolutionary ardour unchanged. She travelled throughout France, preaching revolution, and in 1883 she led a Paris mob which pillaged a baker's shop. For this she was condemned to six years' imprisonment, but was released in 1886, at the same time as Prince Kropotkin and other prominent anarchists. After a short period of freedom she was again arrested for making inflammatory speeches. She was soon liberated, but, hearing that her enemies hoped to intern her in a lunatic asylum, she fled to England. She returned to France in 1895, and in 1902 was back in London. She was touring France and lecturing on behalf of anarchist propaganda when she died at Marseilles on the 20th of January 1905.

Her Mémoires (Paris, 1886) contain accounts of her trials. See also La Bonne Louise (Paris, 1906), by E. Girault.

MICHEL, FRANCISQUE XAVIER (1809–1887), French antiquary, was born at Lyons on the 18th of January 1809. He became known for his editions of French works of the middle ages, and the French Government, recognizing their value, sent him to England (1833) and Scotland (1837) to continue his researches there. In 1839 he was appointed professor of foreign literature in the Faculté des lettres at Bordeaux. Between 1834 and 1842 he published editions of a large number of works written between the eleventh and fourteenth centuries in French, English and Saxon, including the Roman de la rose and the Chanson de Roland. Subsequently he published French translations of Goldsmith, Sterne, Shakespeare and Tennyson. He died in Paris on the 18th of May 1885.

His original works include Histoire des races maudites de la France et de l'Espagne (1847); Recherches sur le commerce pendant le moyen âge (1852–1854); Les Ecossais en France et les français en Ecosse (1862); Études de philologie comparée sur l'argot (1856); Le Pays basque (1857); Histoire du commerce et de la navigation à Bordeaux (1867–1871); and, in conjunction with Edouard Fournier, Histoire des hôtelleries, cabarets, hotels garnis (1851–1854).

MICHELANGELO (MICHELAGNIOLI BUONARROTI) (1475–1564), the most famous of the great Florentine artists of the Renaissance was the son of Ludovico Buonarroti, a poor gentleman of that city, and of his wife Francesca dei Neri. The Buonarroti Simonzi were an old and pure Florentine stock of the Guelf faction: in the days of Michelangelo's fame a connexion of the family with the counts of Canossa was imagined and admitted on both sides, but has no foundation in fact. Ludovico was barely able to live on the income of his estate, but made it his boast that he had never stooped to add to it by mercantile or mechanical pursuits. The favour of the Medici procured him employment in state offices, among them that of podestà or resident magistrate for six months, from the autumn of 1474, at Castello di Chiusi and Caprese in the Casentino. At Caprese, on the 6th of March 1475, his second son Michelagnioli or Michelangelo was born. Immediately afterwards the family returned to Florence, and the child was put to nurse with a marble-worker's wife of Settignano. His mother's health had already, it would seem, begun to fail; at all events in a few years from this time, after she had borne her husband three more sons, she died. While still a young boy Michelangelo determined, in spite of his father's opposition, to be an artist. He had sucked in the passion, as he himself used to say, with his foster-mother's milk. After a sharp struggle his stubborn will overcame his father's pride of gentility, and at thirteen he got himself articled as a paid assistant in the workshop of the brothers Ghirlandaio. Domenico Ghirlandaio, bred a jeweller, had become by this time the foremost painter of Florence. In his service the young Michelangelo laid the foundations of that skill in fresco with which twenty years afterwards he confounded his detractors at Rome. He studied also, like all the Florentine artists of that age, in the Brancacci chapel, where the frescoes of Masaccio, painted some sixty years before, still victoriously held their own; and here, in reply, to a taunt he had flung at a fellow-student, Torrigiano, he received the blow on the nose which disfigured him to his dying day.

Though Michelangelo's earliest studies were directed towards painting, he was by nature and predilection much more inclined to sculpture. In that art he presently received encouragement and training under the eye of an illustrious patron, Lorenzo dei Medici. On the recommendation, it is said, of Ghirlandaio, he was transferred, before the term of his apprenticeship as
Michelangelo's stay in Rome at this time lasted five years—from the summer of 1496 till that of 1501. The interval had been one of extreme political distraction at Florence. The excitement of the French invasion, the mystic and ascetic regime of Savonarola, the reaction which led to his overthrow, and finally the external wars and internal dissidences which preceded a new settlement, had all created an atmosphere most unfavourable to art. Nevertheless Ludovico Buonarroti, who in the troubles of 1494 had lost a small permanent appointment he held in the customs, and had come to regard his son Michelangelo as the mainstay of his house, had been repeatedly urging him to come home. A spirit of family duty and family pride was the ruling principle in all Michelangelo's conduct. During the best years of his life he submitted himself sternly and without a murmur to pinching hardship and almost superhuman labour for the sake of his father and brothers, who were ever selfishly ready to be fed and helped by him. Having now, after an illness, come home in 1501, Michelangelo was requested by the cardinal Francesco Piccolomini to adorn with a number of sculptured figures a shrine already begun in the cathedral of Siena in honour of the most distinguished member of his house, Pope Pius II. Four only of these figures were ever executed, and those not apparently, or only in small part, by the master's hand. A work of greater interest in Florence itself had diverted him from his commission; and this was to provide the execution of the famous colossal statue of David, popularly known as the "Giant." It was carved out of a huge block of marble on which another sculptor, Agostino d'Antonio, had begun unsuccessfully to work forty years before, and which had been lying idle ever since. Michelangelo had here a difficult problem before him. Without much regard to the traditional treatment of the subject or the historical character of his hero, he carved out of the vast but cramped mass of material an adolescent, frowning colossal, tensely watchful and self-balanced in preparation for his great action. The result amazed every beholder by its freedom and science of execution and its victorious energy of expression. All the best artists of Florence were called in council to determine on what site it should be set up, and after much debate the terrace of the palace of the Signory was chosen, in preference to the neighbouring Loggia dei Lanzi. Here accordingly the colossal "David" of Michelangelo took, in the month of May 1504, the place which it continued to hold until in 1882 it was removed for the sake of protection to a hall in the Uffizi Gallery. Time has made it inevitable it should look like and be self-balanced and cabin'd. Other works of sculpture belonging to the same period: among them a second "David," in bronze and on a smaller scale, commissioned by the maréchal Pierre Rohan and left by the young master to be finished by Benedetto da Roverezano, who despatched it to France in 1508; a great rough-hewn "St Matthew" begun but never completed for the cathedral of Florence; a "Madonna and Child" executed on the commission of a merchant of Bruges; and two unfinished bas-reliefs of the same subject.

Neither was Michelangelo idle at the same time as a painter. Leaving disputed works for the moment out of sight, he in these days at any rate painted for his and Raphael's common patron, Angelo Doni, the "Holy Family" now in the Uffizi at Florence. In the autumn of 1504, the year of the completion of the "David," he received from the Florentine state a commission for a work of monumental painting on a heroic scale. Leonardo da Vinci had been for some months engaged on his great cartoon of the "Battle of Anghiari," to be painted on the wall of the hall of the municipal council. The gonfaloniere Piero de' Medici now procured for Michelangelo the commission to design a companion work. Michelangelo chose an incident at the battle of Cascina during the Pisan war of 1564, when the Florentine soldiery had been surprised by the enemy in the act of bathing. He dashed at the task with his accustomed fiery energy, and had carried a great part of the cartoon to completion when, in the early spring of 1505, he broke off the work in order to obey a call to Rome which reached him from Pope Julius II. His unfinished cartoon, in its power over the varieties and contrasts...
of energetic and vitally significant action, showed how greatly Michelangelo had profited by the example of his elder rival, Leonardo, little as, personally, he yielded to Leonardo's charm or could bring himself to do so for his own account. The work of Michelangelo's youth is for the most part comparatively tranquil in character. His early sculpture, showing a great science of anatomy and precision unequalled by the antique, has also something of the antique serenity. It bears strongly the stamp of intellectual research, but not by any means that of stress or strain. In the cartoon of the "Bathers" the qualities afterwards proverbially associated with Michelangelo—his turia, his terribilità, the tempest and hurricane of the spirit which accompanied his unequalled technical mastery and his first found expression.

With Michelangelo's departure to Rome early in 1505 the first part of the life of the great sculptor is over; he might be convenient here to recapitulate its principal results in sculpture and painting, both those preserved and those recorded but imperfectly.

**SCULPTURE.**—Florence, 1490-1504. — "Head of a Faun," marble; lost. — "Kneeling Concert," in the Viceregal Palace. A head in sculpture as a head of an aged faun with a front tooth knocked out, this latter point having been an afterthought suggested by Lorenzo dei Medici. The head is sometimes identified with one in the National Museum at Florence, which however bears no marks of Michelangelo's early style. — "Madonna, Step," bronze; Casa Buonarroti, Florence. This bas-relief, executed in imitation of the technical style of Donatello, is a genuine example of Michelangelo's early work in the Medici school under Bertoldo. The composition and the treatment in both the nude and the ground, genuine work in full relief, of probably somewhat later date than the last-mentioned. The subject occurs often in ancient sarcophagus reliefs: Michelangelo has followed the antique in his conception and treatment of the nude, but the arrangement of the subject is his own.

Bologna, 1494-1495. — Staute of "St Petronius," "St Proculus," and a "Kneeling Angel," marble, and a "Kneeling Lady," marble, in the shrine of St Dominic in the church of that saint at Bologna; the style of both is much in theme the work of Jacopo della Quercia in the same church; the attitude of kneeling angel with the candelabrum imitated from an ancient bas-relief.

Florence, 1495-1506. — "St John in the Wilderness," executed for Lorenzo dei Medici, is remarkable for the perfection of the nude. Declared in 1784 to have been found again in the possession of Count Guandalini-Rossalmini at Pisa. Vehement and prolonged discussion arose as to the authenticity of this newly-found S. Giovanniino, and at last declared for the authenticity of the antique, which is still stoutly maintained. But the finicking and affected elegance of the conception denote a different temperament from Michelangelo's and probably a later date. With this figure must be given up also the head of "Diana," which was said to have been a copy of the Uffizi, which is clearly by the same hand and is claimed also as an early work of Michelangelo. — "Recumbent Cupid," bought by the cardinal San Giorgio as an antique, marble; lost. The attempts to reproduce the existing copy of the violin, which is the best of the antique, especially one now at Turin, must be held mistaken.

Rome, 1495-1501. — "Virgin lamenting the dead Christ," commissioned by the abbot de la Grolée; marble; St Peter's, Rome. — "Baptism," commissioned by the Pico dei Medici family. A figure, nude, presented to the church of St John later, according to the National Museum, Florence. Of these two masterpieces of Michelangelo's youth enough has been said above.

"Cupid," commissioned by the abbot de la Grolée; marble; lost; has been commonly identified with the "Cupid" in the Viceregal Palace, and Albert Museum, but this, if by Michelangelo at all, which is quite certain, must in all likelihood belong to a later time.

Florence, 1501-1506. — Five Saints, in niches decorating the shrine of St John, executed by the Pico dei Medici family for the cathedral of Siena. The contract for the sculptured decoration of this shrine was one of those under which the pressure of other works prevented the artist from ever taking seriously in hand. Of the five saints the first two, Sts. John and Paul, who alone shows any clear marks of his style; the other four were probably designed, and certainly carried out, by weaker hands. — "David" (the "Giante"), commissioned for the city of Florence by Piero Soderini. The city loaned this marble to the Medici, who do not seem to have been satisfied with the work as above. In 1506 it was sold, only to have it added that a wax model in the Casa Buonarroti, showing nearly the same design with a different movement of the legs, is probably Michelangelo's original sketch for the subject.

"David," by Pietro Tacca; bronze; lost; a clay model in the National Museum, Florence. — A bronze, probably by Michelangelo, may be still more the original, if more than one bronze has been brought forward with claims to be the original, but none has stood the test of criticism. "Virgin and Child," commissioned for Taddeo Taddeo; circular relief, unfinished. — "St John," by Pietro Tacca; bronze, lost; a clay model in the National Museum, Florence. Michelangelo's technical skill is probably beyond question, but the vitality and motion of the Christ-child frightened by the flutterings of the bird held out by St John is not in all the world's work; the whole design shows the influence of Leonardo in his gentler, as much as the cartoon of the "Bathers" shows it in his more violent, mood.

"Virgin and Child with St John," commissioned by Bartolommeo Pitti; nearly circular relief, unfinished, marble; Florence, National Museum: a more tranquil and very charming presentent.

"Madonna and Child," sold to the Mouscron family of Bruges (1498).—Michelangelo made the head of St John in that city; group in the round, marble; church of St John, Bruges.

"St Matthew": one of a set of twelve statues of Apostles commissioned by the consuls of the Arte della Lana for the cathedral at Florence; marble; National Museum, Florence. Unfinished; only the head blocked. Michelangelo had not been so much as begun; the contract was signed in 1503 and cancelled in 1505. There is an early drawing by Raphael from this statue.

**PAINTING.**—"Holy Family," painted for Angelo Doni; tempera, canvas, Florence, Uffizi. This is the unworked panel painting of Michelangelo which exists. His love of restless and somewhat strained actions is illustrated by the gesture of the Madonna, who kneels on the ground holding up the child on her right shoulder; her love of the nude by the introduction (wherein he follows Luca Signorelli) of some other wayward undraped figures in the background. "Virgin and Child with Four Angels": tempera; National Gallery, London. This unfinished painting, strongly marked by the influence of Michelangelo in his work at this period, has been confidently claimed for his hand, but lacks his strength and mastery, and is far more probably the work of his imitator and intimate associate, Francesco Granacci. — "Cartoon of the Bathers": late and utterly perished. The only authentic records of it are contained in a few engravings by Agostino Veneziano and a certain number of sketches and studies by the master himself, chiefly at the Albertina, Vienna, the British Museum and the University Galleries, Oxford. An elaborate drawing of many of the figures at Holkham Hall, well known and often engraved, seems to be a later cento destitute of real authority.

Michelangelo had not been long in Rome before Pope Julius devised fit employment for him. That capacious and headstrong fire on great enterprises, had conceived the idea of a sepulchral monument to commemorate his glory when he should be dead, and to be executed according to his own plans while he was still living. He entrusted this congenial task to Michelangelo. The design being approved, the artist was commissioned under the sanction of a decree of 1505-1506 at the quarries of Carrara, superintending the excavation and selecting the necessary marbles. In the spring he returned to Rome. and when the marbles arrived fell to work on the preparations for the work. For a while the pope followed their progress eagerly, and was all kindness to the young sculptor. But presently his disposition changed. In Michelangelo's absence an artist who was no friend of his, Bramante of Urbino, had been selected by Julius to carry out a new architectural scheme, commensurate with the usual vastness of his conceptions, viz. the rebuilding of St Peter's church. To the influence and the malice of Bramante Michelangelo attributed the unwelcome invitation he now received to interrupt the great work of sculpture which he had just begun in order to decorate the Sixtine chapel with frescoes. Soon, however, schemes of war and conquest interposed to divert the thoughts of Julius, not from the progress of his own monument merely, but from artistic enterprises altogether. A few days Michelangelo contrived to say at table to his jeweler that he meant to spend no more money on jewels, either small or great. To add to the artist's discomfiture, which was not going to apply in person for payments due, he was first put off from day to day, and at last actually with scant courtesy dismissed. At this his dark mood got the mastery of him. Convinced that his employment only but his life was threatened, he suddenly took horse and left Rome, and before the messengers of the pope could overtake him was safe on Florentine territory. Michelangelo's flight took place in April 1506. Once among his own people, he turned a deaf ear to all overtures made from Rome for his return, and stayed throughout the summer at Florence, how occupied we are not distinctly informed, but apparently, among other things, on the continuation of his great battle cartoon.

During the same summer Julius planned and executed the victorious military campaign which ended with his unsupported entry at the head of his army into Bologna. Thither, under strict safe-conduct and promises of renewed favour, Michelangelo
was at last persuaded to betake himself. Julius received the
truant artist kindly, as indeed between these two volcanic
natures there existed a natural affinity, and ordered him
his own colossal likeness in bronze, to be set up, as a symbol
of his conquering authority, over the principal entrance
of the church of St Petronius. For the next fifteen months
Michelangelo devoted his whole strength to this new task.
The price at which he undertook it left him, as it turned out,
hardly any margin to subsist on. Moreover in the technical
art of metal casting he was inexperienced, and an assistant
whom he had summoned from Florence proved insubordinate
and had to be dismissed. Nevertheless his genius prevailed
over every hardship and difficulty, and on the 21st of February
1508 the majestic bronze colossus of the seated pope, robed and
mitred, with one hand grasping the keys and the other extended
in a gesture of benediction and command, was duly raised to
its station over the church porch. Three years later it was
destroyed in a revolution. The people of Bologna rose against
the authority of Julius; his delegates and partisans were cast
out, and his effigy hurled from its place. The work of Michel-
angelo, after being trailed in derision through the streets, was
broke up and its fragments cast into the furnace.
Meanwhile the artist himself, as soon as his work was done,
had followed his reconciled master back to Rome. The task
that he had undertaken, however, was after all not the resumption
of the papal monument, but the execution of the series of
paintings in the Sixtine chapel which had been mooted before
his departure. Painting, he always averred, was not his
business; he was aware of his enemy's hopes that a great enter-
prise in fresco-painting would prove beyond his powers; and he
entered with misgiving and reluctance upon his new undertaking.
Destiny, however, so ruled that the work thus thrust upon him
remains his chief title to glory. His history is one of indomitable
will and almost superhuman energy, yet of will that hardly ever
had its way, and of energy continually at war with circumstance.
The only work in which all his life he was able to complete as he
had conceived it was this of the decoration of the Sixtine
ceiling. The pope had at first desired a scheme including figures
of the twelve apostles only. Michelangelo began accordingly,
but could rest content with nought so meagre, and soon proposed
instead a design of many hundred figures embodying the story
of Genesis from the Creation to the Flood, with accessory
personages of prophets and sibyls dreaming on the new dispensa-
tion to come, and, in addition, those of the forefathers of Christ.
The whole was to be enclosed and divided by an elaborate
framework of painted architecture, with a multitude of nameless
human shapes supporting its several members or reposing among
them as if in symbolic repose. In the midst of this meditated
scheme, it was, in the features of the inanimate framework and
those of the great dramatic and prophetic scenes themselves.
The pope bade the artist do as he pleased. By May 1508 the preparations in the chapel had
been completed and the work begun. Later in the same year
Michelangelo summoned a number of assistant painters from
Florence. Trained in the traditions of the earlier Florentine
school, they were unable, it seems, to interpret Michelangelo's
designs in fresco either with sufficient freedom or sufficient
uniformity of style to satisfy him. At any rate he soon dismissed
them, and carried out the remainder of his colossal task alone,
except for the necessary amount of purely mechanical and
subordinate help. The physical conditions of prolonged work,
face upwards, upon this vast expanse of ceiling were adverse and
trying in the extreme. After four and a half years of toil
the painted surface of the arch that MICHELANGELO

was as far as Bologna. This was between September 1510, by which
time the whole of the great series of subjects along the centre
of the vault were completed, and January 1517, when the master
set to work again and began filling the complicated lateral
spaces of his decorative scheme.
The main field of the Sixtine ceiling—in form a depressed barrel
vault—is divided in Michelangelo's scheme into four larger, alterna-
ting with five smaller fields. The following is the order of the
subject, as depicted in the cycle, and the dividing of the light from
the darkness: (1) the creation of man and woman; (2) the creation
of the waters; (4) the creation of man; (5) the creation of woman;
(7) the temptation and expulsions; (8) the deluge; (9) the drunkenness
of Noah. The figures in the last three of these fields are on the
south and north walls of the chapel respectively. In the remaining
fields, five, 1, 3, 5, 7 and 9 of the picture is reduced by the encroachments
of the architectural framework with its seated pairs of prophets,
and common known as "Slaves" or "Atlases." Flanking
these smaller compositions, inclusive delimiting the field of the crown
of the vault and the walls on either side, are seated
figures of prophets and sibyls alternately; two other prophets are
introduced in the 'extreme' of the series—making seven prophets
and five sibyls in all. In the triangles to right and left of the
prophets at the two extremities are the death of Goliath, the death
of Holofernes, the brazen serpent and the punishment of Haman.
In the two lunettes above the windows are the ancestors of Christ, their
names indicating the Moses stories. Thus twelve triangles above them (between the prophets and sibyls)
other kindred groups crouched or sitting. These last are all shown
as enclosed in simple human actions and household relations,
heightened but not falsified into mythic grandeur, into
magnificent significance from roots deep in daily human nature.
The work represents all the powers of Michelangelo at their best. Developing all the accessory allusions of the painter's art, he has
concentrated himself, as it were, the human form and face at their highest power. His imagination has conceived, and
his knowledge and certainty of hand have enabled him to realize,
independently and combinations of unmatched variety and grandeur,
and countenances of unmixed expressiveness and power. But
he has not trusted, as he came later to trust, to science and acquired
knowledge merely; neither do his personages, so far as they did
towards transcendent human possibility or leave the facts of actual
life behind them. To this end his knowledge searching realism serve to embody all this inspiration and sustain all this
sublimity; the sublimity, moreover is combined with the noblest elements of grace and even of tenderness. As for the intellectual
meaning of his vast design, if it be not the same as that we see
represented in a first glance or by a bare description, they are
from the nature of the case inexhaustible, and can never be perfectly
defined. Whatever the soul of this great Florentine, the
intimate heir of Dante, in whom the Christianity of the middle ages
is not shamed in his mind, but expanded and transcendentalized,
by the knowledge and love of Plato; whatever the soul of such a man,
full of suppressed tenderness and righteous indignation, and of
heaviness and contemplation of things eternal, Michelangelo
has expressed or shadowed forth in this great and significant
scheme of paintings. The powers of the artist seem to have expanded
with the progress of his work. He seems to have begun (as the
spectator, of course, coming to the work through the chronolo-
gically last subject of the series, the drunkenness of Noah,
and having worked backwards, increasing the scale of his figures
for their better effect from the fourth subject (the Temptation and
Expulsion), and rising in ascending scale of majesty through the
successive acts of creation from the last to the first.
The Sixtine chapel was no sooner completed than Michelangelo
resumed work upon the marbles for the monument of Julius.
But four months only had passed when Julius died. His heirs
immediately entered (in the summer of 1513) into a new contract
with Michelangelo for the execution of the monument on a
reduced scale. What the precise nature and extent of the original
design had been we do not know, only that the monument
was to be detached from the wall, and to stand four-square
and free—a thing hitherto unknown in Renaissance sepulchral
architecture—in one of the chapels of St Peter's. But the new
contract, which consisted of a great three-sided structure, two courses high, projecting from the church wall, and decorated on its three unattached
sides with statues. On the upper course was to be placed the
colossal recumbent figures of the pope, with a vision of the
Virgin and Child above him, angels mourning at the sides,
and prophetic and allegoric personages at the angles—sixteen
figures in all. The lower course was to be enriched with twenty-
four figures in niches and on projecting pedestals: in the
niches, Victories; in front of terminal pilasters between them,

MICHELANGELO

305
slaves or captives denoting, it would seem, either conquered provinces or arts and sciences in bondage after their patron's death, much injured and indisputable sketch by the master at Berlin, with a copy of the same by Sacchetti, are supposed to show the design at this stage of its reduction. The entire work was to be completed in nine years' time. During the next three years, it would seem, Michelangelo brought to completion three of the original figures, for which the blocks had reached Rome from Carrara as early as July 1508; and they are among the most famous of all existing works of the sculptor's art—namely, the "Moses," now in the church of S. Pietro in Vincoli at Rome and the "Two Slaves" at the Louvre.

The "Moses," originally intended for one of the angles of the upper course, is now placed at the level of the eve, in the centre of the principal face of the monument as it was at last finished, on a deflorately reduced and altered scale, by Michelangelo and his assistants in his old age. The prophet, supposed to have just come down from Mount Sinai and found the Israelites worshipping the golden calf, sits, heavily bearded and draped, with only his right arm bare, his left foot drawn back, his head raised and turned to the left, his left hand laid on his lap and his right grasping the tables of the law—an incarnation of majestic indignation and menace. The work, except in one or two places, is of the utmost finish, and the statue itself is one of the noblest contrivances of the entire design done in marble. The "Slaves" at the Louvre are youthful male figures of equally perfect execution, nude but for the band which passes over the breast of one and the right leg of the other. One, with his left hand raised to his head and his right pressed to his bosom, his eyes almost closed, seems succumbing to the agonies of death; the other, with his arms bound behind his back, looks upward still hopelessly struggling. All three of these figures were finished between 1513 and 1516.

By 1516 Michelangelo's evil star was again in the ascendancy. Julius II. had been succeeded on the papal throne by Cardinal Giovanni de' Medici under the title of Leo X. The Medici, too, had about the same time by force and fraud re-established their sway in Florence, overthrowing the free institutions that had prevailed there since the days of Savonarola. Now, on the one hand, this family were the hereditary friends and patrons of Michelangelo; on the other hand he was a pacifist and a republican Florence; so that henceforward his personal allegiance and his political sympathies were in conflict. Over much of his art, as has been thought, the pain and perplexity of this conflict have cast their shadow. For the present the consequence to him of the rise to power of the Medici was a fresh interruption of his cherished work on the tomb of Julius. Leo X. and his kinsmen were full of a vast new scheme for the enrichment and adornment of the façade of their own family church of San Lorenzo in Florence. Michelangelo, carried away by the idea and forgetful of his other still great and onerous task, offered his services for the new façade. They were eagerly accepted, although for a moment the idea had been entertained of entrusting the work to Leonardo da Vinci. The heirs of Julius on their part showed an accommodating temper, and at the request of Leo allowed their three-years-old contract to be cancelled in favour of another, whereby the scale and sculpture were reduced to two-thirds of the original design, and the work was partly half. Michelangelo soon produced for the San Lorenzo façade a design of combined sculpture and architecture as splendid and ambitious in its way as had been that for the original monument of Julius. The contract was signed in January 1518, and the artist went to Carrara to superintend the excavation of the marbles.

Michelangelo was now in his forty-fourth year. Though half his life was yet to come, yet its best days had, as it proved, been spent. All the hindrances which he had encountered hitherto were as nothing to those which began to beset him now. For the supply of materials for the façade of San Lorenzo he had set a firm of masons to work, and had himself, it seems, entered into a kind of partnership with them, at Carrara, where he knew the quarries well, and where the industry was hereditary and well understood. When all was well in progress there under his own eye, reasons of state induced the Medici and the Florentine magistracy to bid him resort instead to certain new quarries at Pietrasanta, near Serresvalle in the territory of Florence. Hither, to the disgust of his old clients at Carrara and to his own, Michelangelo accordingly had to transfer the scene of his labours. Presently he found himself so impeded and dragged by the mechanical difficulties of raising and transporting the marbles, and by the disloyalty and incompetence of those with whom he had to deal, that he was fain to throw up the commission altogether. The contracts for the façade of San Lorenzo were rescinded in March 1518, and the whole magnificent scheme came to nothing. Michelangelo then returned to Florence, where proposals of work poured in on him from many quarters. The king of France desired something from his hand to place beside the two pictures he possessed by Raphael. The authorities of Bologna wanted him to design a façade for their church of St. Petronius; those of Genoa to cast a statue in bronze of their great commander, Andrea Doria. Cardinal Grimani begged hard for any picture or statue he might have to spare; other amateurs importuned him for so much as a pencil drawing or sketch. Lastly his friend and partisan Sebastian del Piombo at Rome, ever eager to keep up the feud between the followers of Michelangelo and those of Raphael, besought him on Raphael's death to return at once to Rome, and take out of the hands of the dead master's pupils the work of painting still remaining to be done in the Vatican chambers. Michelangelo complied with none of these requests. All that we certainly know of his doing between 1518 and 1523 is the blocking out in the rough of four more of the "Slaves" for the tomb of Julius, and carrying out a commission, which he had received from three citizens of Rome as early as 1514, for a statue of the risen Christ. The roughed-out "Slaves" now stand immured in a grotto in the Boboli Gardens, Florence; the Christ, practically finished by the master but with the last touches added by pupils, stands in the church, for which it was destined, of Sta Maria sopra Minerva at Rome; there is little in it either of devotional spirit or imaginative power, although, in those parts which Michelangelo himself finished, there is extreme accomplishment of design and workmanship.

The next twelve years of Michelangelo's life (1522-1534) were spent at Florence, and again employed principally in the service of his capricious and ungrateful patrons—the Medici. The plan of a great group of monuments to deceased members of this family, to be set up in a new sacristy or mortuary chapel in San Lorenzo, was first broached to Michelangelo in 1526 by Cardinal Giulio de' Medici. No practical impulse, however, was given to the work until Giulio, after the death of Leo X. and the brief pontificate of the puritanical and iconoclastic Adrian VI., had in his turn become pope in 1523 under the title of Clement VII. Even then the impulse was a wavering one. First Clement proposed to associate another artist, Sansovino, with Michelangelo in his task. This proposal being on Michelangelo's peremptory demand abandoned, Clement next distracted the artist with an order for a new architectural design—that, namely, for the proposed Medicean or "Lauren- tian" chapel. When at last after many changes of scope and scheme the plans for this supposed chapel were finally settled, and took shape, they did not include, as had been at first intended, memorials to the founders of the house's greatness, Cosimo (pater patriae) and Lorenzo the Magnificent, or even to Pope Leo X. himself, but only to two younger members of the house lately deceased, Giuliano, duke of Nemours, and Lorenzo, duke of Urbino. Michelangelo brooded long over various designs for this work, and was still engaged on its execution—his time being partly also taken up by the building-plans for the Medicean library—when political revolutions interposed to divert his industry. In 1527 came to pass the sack of Rome by the Austrians, and the apparently irretrievable ruin of Pope Clement. The Florentines seized the occasion to expel the Medici from their city, and set up a free republican government once more. Naturally no more funds for the works in San Lorenzo were forthcoming, and Michelangelo, on the invitation of the new signory, occupied himself for a while with designs for a group of Hercules and Cacus, and another of Samson
and the Philistines—the latter to be wrought out of a block of marble which had been rough-hewn already for another purpose by Baccio Bandinelli. Soon, however, he was called to help in defending the city itself from danger. Clement and his enemy Charles V. having become reconciled, both alike were now bent on bringing Florence again under the rule of the Medici. In view of the approaching siege, Michelangelo was appointed engineer-in-chief of the fortifications. He spent the early summer of 1529 in strengthening the defences of San Miniato; from July to September he was absent on a diplomatic mission to Ferrara and Venice. Returning in the middle of the latter month, he found the cause of Florence hopeless from internal treachery and from the overwhelming strength of her enemies. One of his dark seizures overcame him, and he departed again suddenly for Venice. There for a while he remained, negotiating for a future residence in France. Then, while the siege was still in progress, he returned once more to Florence; but in the final death-struggle of her liberties he bore no part.

When in 1530 the city submitted to her conquerors, no mercy was shown to most of those who had taken part in her defence. Michelangelo himself was spared, on the recommendation of the intervention of Baccio Valori he was presently taken back into favour and employment by Pope Clement. For four years more he continued to work at intervals on the completion of the Medici monuments, with the help from 1532 of Giovanni Montorsoli and other pupils, and on the building of the Laurentian library. In 1531 he suffered a severe illness; in 1532 he made a long stay at Rome, and entered upon yet another contract for the completion of the Julian monument, to be reduced now to a still more shrunken scale and to be placed not in St Peter's but in the church of San Pietro in Vincoli. In the autumn of 1534 he left Florence for good. What remained to be done in the Medici chapel was done by pupils, and the chapel was not finally opened to view until 1545.

The statutes of the Medici monument take rank beside the "Moses" and the "Dying Slave" of Donatello as the finest work of Michelangelo's in material in sculpture. They consist of a Madonna and Child and of the two famous groups, each composed of an armed and seated portrait-stature in a niche, with two emblematic figures reeling on each side of a sarcophagus below. The "Madonna and Child" (left unfinished because the marble was short in bulk) combines astonishingly the divers qualities of realistic motive and natural animation with learned complexity of design and imposing majesty of effect. It was set up finally—not at all in accordance with the artist's first bent and inclination, but bequeathed to posterity in its present form, a happy and confident practical survey immediately preceding action. To this contrast of the meditative and active characters corresponds a contrast in the emblematic groups accompanying the portraits. At the side of "Evening," the
time in sculpture. scheme; in niches at either side of him were to be standing figures of "Leah" and "Rachel." These Michelangelo himself executed hastily with the help of assistants. To pupils entirely was left the carrying out of the upper cornice, with the recumbent effigy of the pope on horseback, an idea from a weak and incongruous architectural scheme, a Madonna and Child in a niche above, and a prophet and a sibyl in recesses at either side. Meantime all idea of incorporating any of the "Slaves" in the new design had been abandoned, and the group that had been intended for the pulpits of 1513-1516 to Roberti Strozzi, who gave them to Francis I.; but the four that had been roughed out between 1518 and 1522 remained at Florence. "Brutus," marble (National Museum, Florence). Probably executed after 1523 for "the Count Ludovico de' Medici. To the end of this period or to a year or two later belongs the infinitely pathetic unfinished sketch in marble of a life-size "Pieta" (Palazzo Condini, Rome)—the mourning mother, standing on an elevation—of immense tragic power in its weight and size. But still later, after 1545, there are more complicated and more finished group of the "Pieta," with the corpse of Christ collapsing in utter relaxation through the arms of those who try to uphold it; this Michelangelo did for his own sepulchre. Stanzas and other decorative figures.

PAINTING.—The Entombment of Christ (National Gallery, London). This unfinished painting bears all the marks of Michelangelo's design, and must have been begun from a cartoon by him, perhaps as early as 1540 or 1541. It is evident in some parts, particularly the body of Christ; other parts, in various degrees of incompleteness, are apparently the work of various pupils or imitators.

In all his life-works mentioned above, preparatory sketches and studies by the master's hand exist. These, with a large number of other drawings, finished and unfinished, done for their own sakes and not for any ultimate use, are of infinite value and comfort to the artist. Michelangelo was the most profound scientific as well as the most inspired and daring of draughtsmen, and from boyhood to extreme old age never ceased to practise with pen, chalk or pencil. He is said to have burned vast numbers of his own sketches, to be carried about his body, and caused others to be burned. Others were given to friends and pupils to whom he had given them; so that what we possess must be less than a tithe of what he executed. But there are some 250 genuine sheets—enough to let us follow up and understand and appreciate the stages of his life in the mastering his designs at all periods of his life. They are scattered amongst various collections, chiefly public; those in England (at the British Museum, the University Galleries, Oxford, and the Royal Library, Windsor); those at the Vatican, the Uffizi, the Albertina, and the Medici. The finest examples remain still at what was for centuries the home of his heirs, the Casa Buonarroti at Florence; others at the Uffizi, Florence; the Venice Academy; the Albertina, Vienna; the Louvre; the Conde Museum at Chantilly; the Berlin Museum; and, not least, the Teyler Museum at Haarlem. By means of these drawings and the many published facsimiles we are best able to trace the progress of the master's genius and its secrets. We see him diligently copying in youth the earliest works of Giorgio, Masaccio, and his own master Ghirlandajo. At this date his instinct was that all of design was to be treated in a manner of hatching: sometimes extremely careful and close, at other times more bold and free, and in either case all his own. Sketches and studies in every stage exist for the "David," the "Bathers Surprised," the accessory figures for the tomb of Julius II. By his first conception, and the great series of the Sixtine Chapel decorations. By, or even before the date of the Sixtine Chapel, chalk, red or black, conveys the idea of such use of the pen, and many of the finest studies for the "Slaves" or Atlantes are in the latter material (many more studies are preserved for these subordinate figures than for the main compositions). After the Sixtine Chapel period the pen gives way to red or black chalk almost exclusively. In the "Annunciation to the Virgin" (in the possession of the Medici family, Florence) of about 1532-1535, he began the practice of making highly finished and fully shaded drawings of classic or symbolic subjects in red or black chalk for presentation to his friends or pupils; and circles of artists were to be seen each, with a passionate Platonic affection, from about 1532. The "Fall of Phaeton," the "Titans," the "Ganymede," the "Men shooting at a Mark," are well-known examples; in this class of work the Windsor collection is rich. At this time the power of Michelangelo's hand was more than ever developed; he produced drawings little less powerful and finished of Christian subjects, especially the "Crucifixion," the "Entombment" and "Resurrection." Then comes the great fresco of the "Last Judgment," for which the most obvious classical and Christian subjects were selected. Few extant drawings for the Cappella Paolina a flattering both of the imagination and of the hand become discernible. To the same or to still later years belong many beautiful but somewhat tentative drawings done either directly for, or nearly in the spirit of, the famous "Crucifixion" which he is recorded to have painted with so much devotion for Vittoria Colonna. About many of these, for their intensity of feeling, there is a wakening touch betraying the approach of infamy; so there is about many of the architectural studies for the buildings of which he had charge in his last years at Rome; but signs of the old impressive power and penetration are not wanting in some even of the latest drawings that have come down to us.

During his later years the long-pent human elements of fervour and tenderness in Michelangelo's nature had found vent and utterance such as they had never found before. He had occasionally practised poetry in youth, and there are signs of some transient love-passages during his life at Bologna. But it was not until towards his sixtieth year that the springs of feeling were fairly opened in the heart of this solitary, this intense, this cold and iron-souled artist of the "capriccio" and iron-time; life-weary and laboured-artisted of the About 1532-1540, we find him beginning to address impassioned sonnets—of which the sentiment is curiously comparable to that expressed in some Shakespeare's—to a beautiful and gifted youth, the young Roman noble Tommaso Cavallieri. Soon afterwards he made the acquaintance of the pious, accomplished, and high-souled lady, Vittoria Colonna, widow of the Marquess Pescara. For ten years until her death, which happened in 1547, her friendship was the great solace of Michelangelo's life. On her, in all loyalty and reverence, he poured out all the treasures of his mind and all his imprisoned powers of tenderness and devotion. She was the chief inspirer of his poetry—of which, along with her praises, the main themes are the Christian religion, the joys of Platonic love, and the power and mysteries of art. Michelangelo's poetical style is stern and concentrated like the man. He wrote with labour and much self-correction; we seem to feel him clinging firmly on the material, and overcome by the same overwhelming energy and vehemence with which contemporaries describe him as clinging himself on the material of marble—the same impetuosity of temperament combined with the same fierce desire of perfection, but with far less either of innate instinct for the material or of trained mastery over its difficulties.

And so the mighty sculptor, painter, and poet reached old age. An infamy which settled on him in 1544, and the death of Vittoria Colonna in 1547, left him broken in health and heart. But his strength held on for many a year longer yet. His father and brothers were dead, and his family sentiment centered itself on a nephew, Leonardo, to whom he showed unremitting practical kindness, coupled with his usual suspiciousness and futilness of temper. In almost all his relations the old man continued to the end to manifest the same loyal and righteous heart, accompanied by the same masterful, moody, and tremendous energy. And the younger generation he held a position of absolute ascendency and authority; nor was it his example, as we have said, by any means altogether salutary for them. To artists, and to a certain number of chosen friends, belonging chiefly to the lettered, diplomatic, and secretarial classes, he was more accessible and amiable than he had been to any one in earlier days, though still formidable in modes of scorn and scoffing. His great age and fame made him the most honoured citizen of Rome, to whom the highest, both of his fellow countrymen and foreigners, were eager to do homage. During the last years of his life he made but few more essays in sculpture, and those not successful, but was much employed in the fourth art in which he excelled—that of architecture. A succession of popes demanded his services for the embellishment of Rome. Between 1536 and 1546 he was engaged on plans for the rearrangement and restoration of the Lateran, the design of a new building, and the project of altering the Capitol plans which were only partially and imperfectly carried out during his lifetime and after his death. For Paul III. he finished the palace called after the name of the pope's family the Farnese. On the death of Antonio da San Gallo he succeeded to the onerous and coveted office of chief architect of St Peter's church, for which he remodelled all the designs, living to see some of the main features, including the supports and lower portion of the great central dome, carried out in spite of all obstacles, according to his plans. The dome as it stands is his most conspicuous and one of his noblest monuments: the body of the church was completed in a manner quite different from his devising. Other
great architectural tasks on which he was engaged were the reconstruction of the Porta Pia, and the conversion of a portion of the baths of Diocletian into the church of Sta Maria degli Angeli; the great cloister with its hundred columns, which is considered the most magnificent part of this reconstruction which remains as he designed it. At length, in the midst of these vast schemes and responsibilities, the heroic old man's last remains of strength gave way. He died on the threshold of his ninetieth year, on the 18th of February 1564.

Authors.—For the earlier bibliography of Michelangelo, which is extensive, see the useful though very imperfect compilation of Passerini, Bibliografia di Michelangelo Buonarroti, &c. (Florence, 1875). The most important works, taken in chronological order, are the following: of the fragmentary Dialogus de viris illustribus, written soon after 1571, first published by Tiraboschi, Storia della letteratura italiana (Modena, 1811); G. Vasari, in Vita degli più eccellenti architetti, pittori, e scultori, Florence, 1550; Michelangelo Buonarroti (1553); this account, for which the author, a pupil and friend of the master's, had long been collecting materials, was much fuller than that of Vasari, who made use of it in rewriting his own life of Michelangelo for his second edition, which appeared after the master's death (1568). The best edition of Vasari is that by Milanesi (Florence 1878-1883); of Condivi, that by Gori and Marietti (Pisa, 1745); for English readers there is a useful translation with notes by C. Symonds, The Life of Michelangelo, London, 1891. Inconclusive editions are those published by Bottari, Raccolte di lettera sulla pittura, &c. (Rome, 1754; 2nd ed. by Tizocoi, Milan, 1822); the next by Gaye, Carteggio inedito (1840). Portions of the correspondence preserved in the archives of the Pitti family were published by C. Laplante, Inediti della Rima di Michelangelo Buonarroti (1863), and by Daelli in Carte Michelangeliche inedite (Milan, 1865). Complete biographies of Michelangelo had been meanwhile attempted by J. Harford (London, 1855), which, however, was criticized by W. Passerini, Dea Michelangelis inanis (Hanover, 5th ed., 1879). A great increment of biographical material was at length obtained by the publication, in the four hundredth year after Michelangelo's birth, of the whole body of his letters by R. Milanesi, published in a similar manner to those other volumes, the Rime di Michelangelo Buonarroti, ed. G. Milanesi (Florence, 1875). This material was first employed in a connected but too trivial narrative by A. Gotti, Vite di Michelangelo (Florence, 1875). Next followed C. Heath Wilson, ed., Michelangelo, London, 1884; a work which is entitled to a place in the technical remarks in which, especially as concerns the frescoes, are still valuable. Other lives of Michelangelo are by Anton Springer, in his Michelangelo u. Raphael (Leipzig, 1883); J. A. Symonds, The Life of Michelangelo (London, 1893), full of valuable matter on the history and spirit of Michelangelo's times, but not trustworthy in the criticism of his works; H. Mackowsky, Michelangelo (Berlin, 1908), excellent in all respects, and in moderate compression; F. G. Martineau, Michelangelo: a Handbook (London, 1895); Consult also, C. Jules Michelet, Jules Michelet (Leipzig, 1903), and with caution H. Thode, Michelangelo u. das Ende der Renaissance (Berlin, 1902-1903).

The poems of Michelangelo the first sound edition is that already referred to, G. Guasti, Rime di Michelangelo Buonarroti (1863); in earlier editions the text had been recklessly tampered with, and the rugged individuality of the master's style smoothed down. An edition with German translations was published by Hasenclever (Leipzig, 1875); and a thorough critical edition by K. Frey, Michelangelo, 2 vols. (Leipzig, 1897). The most valuable work, the translation of the master's letter to his pupils, is that by J. A. Symonds, in Sonnets of Michelangelo and Campanella (London, 1878) are invaluable. On the drawings of Michelangelo see especially B. Berenson, The Drawings of Florentine Painters, (London, 1903). A convenient and exhaustive work is that of F. G. Martineau, Michelangelo und seine Werke (Leipzig, 1898).}

**Michelet, Jules (1798-1874)**, French historian, was born at Paris on the 21st of August 1798, of a family which had Huguenot traditions. His father was a master printer, not very prosperous, and the son at an early age assisted him in the actual work of the press. A place was offered him in the imperial printing office, but his father was able to send him to the famous Collège or Lycée Charlemagne, where he distinguished himself. He passed the university examination in 1821, and was shortly after appointed to a professorship of history in the Collège Rollin. Soon after this, in 1824, he married. The period of the restoration and the July monarchy was one of the most favourable to rising men of letters of a somewhat scholastic cast that has ever been known in France, and Michelet had powerful patrons in Villemain, Victor Cousin and others. But, though he was an ardent politician (having from his childhood embraced republicanism and a peculiar variety of romantic free-thought), he was first of all a man of letters and an inquirer into the history of the past.

His earliest works were school-books, and they were written at a very early age. Between 1825 and 1827 he produced divers sketches, chronological tables, &c., of modern history. His Pré cis de l'histoire universelle showed a very promising exhibition of the historical and literary power of the writer to greater advantage, but also displaying the peculiar visionary qualities which made Michelet the most stimulating, but the most untrustworthy (not in facts, which he never consciously falsified, but in suggestion) of all historians. The events of 1830 had unmuzzled him, and had put him in a better position for study by obtaining for him a place in the Record Office, and a deputy-professorship under Guizot in the literary faculty of the university. Very soon afterwards he began his chief and monumental work, the Histoire de France. But he accompanied this with numerous other books, chiefly of erudition, such as the Œuvres choisies de Vico, the Mémoires de Luther écrites par lui-même, the Origines du droit français, and somewhat later the Proces des templiers. 1838 was a year of great importance in Michelet's life. He was in the full height of his powers, his studies had fed his natural aversion to the principles of the Jesuits, and brought him into ecclesiasticism, and at a moment when the revived activity of the Jesuits caused some real and more pretended alarm he was appointed to the chair of history at the Collège de France. Assisted by his friend Edgar Quinet, he began a violent polemic against the unpopular order and the principles which it represented, a polemic which made their lectures, and especially Michelet's, one of the most popular resorts of the day. He published, in 1839, his Histoire romaine, but this was in his graver and earlier manner. The results of his lectures appeared in the volumes Le Prêtre, la femme, et la famille et le peuple. These books do not display the apocalyptic style which, partly borrowed from Lamennais, characterizes Michelet's later works, but they contain in miniature almost the whole of his curious ethical-political-religious creed—a mixture of sentimentalism, communism, and anti-sacerdotalism, supported by the most eccentric arguments, but urged with a great deal of eloquence. The principles of the outbreak of 1830 and the early days of the July Monarchy was not the least important of those who conditioned and propagated them: indeed his original lectures were of so incendiary a kind that the course had to be interdicted. But when the actual revolution broke out Michelet, unlike many other men of letters, did not attempt to enter on active political life, and merely devoted himself more strenuously to his literary work. Besides continuing the great history, he undertook and carried out, during the years between the downfall of Louis Philippe and the final establishment of Napoleon III., an enthusiastic Histoire de la révolution française. Despite or because of its enthusiasm, this was by no means Michelet's best book. The events were too near and too well known, and hardly admitted the picturesque sallies into the blue distance which make the charm and the danger of his larger work. In actual picturesque ness as well as in general veracity of picture, the book cannot approach Carlyle's; while as a mere chronicle of the events it is inferior to half a dozen prosaic histories older and younger than itself.
Michelet, K. L.—Michelet, Karl Ludwig (1801–1893), German philosopher, was born on the 4th of December 1801, at Berlin, where he died on the 10th of December 1893. He studied at the Gymnasium and at the University of his native town, took his degree as doctor of philosophy in 1824, and became professor in 1829, a post which he retained till his death. Educated in the doctrine of Hegel, he remained faithful to his master all his life, defending and continuing the Hegelian tradition. His first notable work was the System der philosophischen Moral (Berlin, 1828), an examination of the ethical theory of responsibility. In 1836 he published, in Paris, a treatise on the Metaphysics of Aristotle, written in French and crowned by the Académie des Sciences Morales et Politiques. He wrote also two other treatises on Aristotle: Nikomachische Ethik (2nd ed., 1848) and Die Ethik des Aristoteles in ihrem Verhältniss zum System der Moral (1857). His own views are best expressed in his Vorlesungen über die Persönlichkeit Gottes (1841) and Die Epiphänomen der ewigen Persönlichkeit des Gottes. The philosophical theology developed in these works has been described as a "Neo-Christian Spirituality."

Among his other publications may be mentioned Geschichte der Leib und der Seele des Menschen von Kants bis Hegels (1857–1858); Anthropologie und Psychologie (1840); Essai de logique (Paris, 1856); Naturrecht oder Rechtsphilosophie (1866); Hegel der unverwählte Weltphilosoph (1870), Wahrheit aus meinem Leben (1881). In 1859 Michaelis was engaged in publishing the complete works of Hegel, and in 1875 he founded the Berlin Philosophical Society, which has continuously represented the Hegelianism of Germany. He was the first editor of Der Gedanke (1860), the official organ of the society.

Michelet, John (1744–1793), English natural philosopher and geologist, was born in 1744 and educated at Queens' College, Cambridge. His name appears fourth in the Tripos lists for 1748–1749; and in 1755 he was moderator in that examination. He became M.A. in 1754, and B.D. in 1761. He was a fellow of his college, and was appointed Woodwardian professor of geology in 1762, and in 1767 rector of Thornhill in Yorkshire, where he died on the 29th of April 1793. He was
MICHEL OF NORTHGATE—MICHIGAN

MICHEL OF NORTHGATE, DAN (fl. 1340), English writer, the author of the *Ayenbite of Inwy*.

Nothing is known of him except what can be gathered from his work. It is a literal translation in the Kentish dialect of a French treatise entitled *Le Somme des vices et des vertus* (also known as *Le Miroir du monde ou Le Livre des commandemens*, &c.), which was written in 1270 by Laurentius Gallus, a Dominican monk and confessor to Philip III. of France. This work was translated into Flemish, Catalanian, Spanish, and Italian, and appears in no less than six English translations. Dan Michel's autograph MS. is preserved in Arundel MS. 57, which states that the work was completed in the year 1340 on the eve of the apostles Simon and Jude by Dan Michel of Northgate, a brother of the cloister of St Austin of Canterbury. The value of the book is chiefly philological as an authenticated and dated example of the southern dialect.

The *Ayenbite of Inwy* was edited for the Roxburghe Club by the Rev Joseph Stevenson in 1855, and for the Early English Text Soc. by Richard Morris in 1876.

MICHELLOZZO DI BARTOLOMEO (1391-1472), Italian sculptor, was a Florentine by birth, the son of a tailor, and in early life a pupil of Donatello. He worked in marble, bronze, and silver. The statue of the young St John over the door of the Duomo at Florence, opposite the Baptistery, is his; and he also made the beautiful silver statue of the Baptist on the altar-frontal of San Giovanni. Michelozzo's great friend and patron was Cosimo de' Medici, whom he accompanied to Venice in 1433 during his short exile. While at Venice, Michelozzo built the library of San Giorgio Maggiore, and designed other buildings there. In 1428, together with Donatello, he erected an open-air pulpit at an angle of the cathedral of St Stephen at Prato. The magnificent Palazzo dei Medici at Florence built by Cosimo, was designed by him; it is one of the noblest specimens of Italian 15th-century architecture, in which the great taste and skill of the architect has combined the delicate lightness of the earlier Italian Gothic with the massive stateliness of the classical style. With great engineering skill Michelozzo shored up, and partly rebuilt, the Palazzo Vecchio, then in a ruinous condition, and added to it many important rooms and staircases. When, in 1437, through Cosimo's liberality, the monastery of San Marco at Florence was handed over to the Dominicans of Fiesole, Michelozzo was employed to rebuild the domestic part and remodel the church. For Cosimo I. he designed numerous other buildings, mostly of great beauty and importance. Among these were a guest-house at Jerusalem for the use of Florentine pilgrims. Cosimo's summer villa at Careggi, is one of the strong fortified palaces of S. Croce at Fiesole. For Giovanni di Medici, Cosimo's son, he built a very large and magnificent palace at Fiesole. In spite of Vasari's statement that he died at the age of sixty-eight, he appears to have lived till 1472. He is buried in the monastery of San Marco, Florence. Though skilled both as a sculptor and engineer, his fame chiefly rests on his architectural works, which claim for him a position of very high honour even among the greatest names of the great 15th-century Florentines.

MICHIGAN, a north central state of the United States, situated between latitudes 41° 44' and 47° 30' N. and latitudes 82° 25' and 90° 31' W., and consisting of two peninsulas—the upper or northern and the lower or southern—separated by a strait. The upper or northern peninsula is bounded N. by Lake Superior; E. by lakes Superior, George, Huron, and Michigan, and by St Mary's River, which separates it from the Province of Ontario, Canada; S. by lakes Huron and Michigan and the Straits of Mackinac, which separate it from the lower peninsula; and S. and W. by Wisconsin, and the Menominee, Montreal and Brule Rivers, which separate it in part from Wisconsin. The lower or southern peninsula is bounded N. by lakes Michigan and Huron and the Straits of Mackinac. E. by lake Huron and the Great Lakes; S. by lakes Clair and Detroit Rivers, which separate it from Ontario; S. by Ohio and Indiana, and W. by Lake Michigan. In size Michigan ranks eighteenth among the states of the Union, its total area being 57,980 sq. m., of which 500 sq. m. are water surface.  

Physical Features.—Physiographically the history of the state is similar to that of Minnesota. The northern part is rugged mountainous "old land," not completely worn down by erosion; and the southern part is a part of a coastal plain, whose layers contain salt, gypsum and some inferior coal. Lake Huron on the east and Lake Michigan on the west of the lower peninsula are each 581 ft. above sea-level, and Lake Superior on the north of the upper peninsula is 812 ft. above sea-level. Fort Miamis, part of the surface of the state is gently undulating and at an slight elevation above the lakes, but low marsh lands are common to many sections; the north part of the lower peninsula is occupied by a plateau of considerable dimensions, and the north-west part of the upper peninsula is rugged with many small mountains and the lower peninsula from Saginaw Bay west by south through the valleys of the Saginaw, Maple and Grand rivers, is a depression—the former channel of an old glacial river—in which elevations for a considerable area are less than 100 ft. above the lakes. To the south-east of this depression is a water-parting with summits varying from about 400 to 600 ft. above the lakes extends from a point between Saginaw Bay and Lake Huron south by west to the south border of the state and beyond. The east slope descends quite rapidly to a low flat belt from 5 to 40 m. wide along the east border of the state south from Lake Huron. From Lake Huron to the south-east shore of Saginaw Bay a wide sandy beach is followed northward by precipitous shores aboding in rocks and bluffs. West of the divide and south of the state from Lake Michigan there is an elevation formed by the valleys of the St Joseph, Kalamazoo and Grand rivers, by the gently rolling uplands that form the parting divides between them, and by sand dunes, which here and there rise to a height of from 100 to 200 ft. above the lake shore. West of the state on the Wisconsin side (but not on the Wisconsin side) of the lake by the prevailing west winds. The north and north-west portions of the state—including the counties of Roscommon and Missaukee, part of Mecosta and all of Lake county—are occupied by a rolling plateau which attains an elevation at its highest point, north of its centre, of upwards of 1100 ft. above Lake Michigan; to the south of this plateau the land slopes gently down to the depression and to the low shores of Lake Michigan and Saginaw Bay. The surface of the upper

1 This is the northernmost point of the mainland; the most northerly of the islands north-east of Isle Royal and belonging to Michigan is more than 40' further north.

2 In addition, within the boundaries of Michigan, are approximately 15,653 sq. m. of Lake Superior, 12,992 sq. m. of Lake Michigan, 9925 sq. m. of Lake Huron and 460 sq. m. of lakes St Clair and Erie.
peninsula is more irregular than that of the lower peninsula. A portion extending through the middle from east to west and south, from west of the centre to Green Bay, is either flat and even swampy or only gently undulating. Eastward from Green Bay are two ranges of hills, one lying the south shore and ranging from 30 to 300 ft. in height, the other close to or touching the north shore and reaching in places an elevation of 600 ft. above Lake Superior. The famous Pictured Rocks in Alger county on the lake shore, east of Marquette, are perhaps the most picturesque. A portion of the state farther west. South and south-east of Keweenaw Bay, in the Marquette iron district, is an irregular area of islands, mountains, swamps, and lakes, some of the mountain peaks of the Huron Mountains (in Marquette county) rising to an elevation of 1000 ft. above the level of the lake. The Porcupine Mountains (2032 ft. above the sea) in the north-west part of Ontonagon county are the highest in the state. To the south of this is the Menominee iron district, marked somewhat regularly by east and west, extending in a general north southerly direction through Keweenaw peninsula to the Wisconsin border and beyond is the middle of three approximately parallel ranges, separated from each other by flat land, with here and there an isolated peak. Sandstone formations, called the Detroit formation, are found near the surface. The larger of these lakes have a sluggish flow; but many of the larger streams of the lower peninsula have sufficient fall to furnish a large amount of water power, while the small streams that flow into Lake Superior from the central portion of the state have east, west, and south. Ash from several of these, have several falls and rapids; in places also they are lined with steep, high banks. Most of the larger rivers of the state, the Muskegon, Grand, St. Joseph, Manistee, and Kalamazoo, are in the west portion of the state peninsula. A number of thousands of lakes of clear water are dotted over the state; nearly all the surface of the state, and many of them are lined with picturesque woodland shores. Islands in lakes Superior, Michigan, and Huron are scarcely less numerous. Fruits and Flora.—Michigan, especially the north portion, still almost entirely wild. The black beech, birch, elm, hickory, porcupine, fox, squirrels, hares, rabbits, musk rats, minks, weasels, skunks and woodchucks. Among animal life is great, ("Bob White") partridges, grouse, geese, woodcocks, snapping turtles, long snapping turtles, thrushes, bobolink, oriole, chickadee, meadow-lark, cat-bird, bluebird, wrens and warblers. Among flies, white fish, lake trout, perch, herring, sun-fish, bass, sturgeon, pickerel, suckers, German carp, and smelt from about the lakes. The speckled trout thrives in many of the streams. Before it was settled by the whites the area now included in Michigan was a forest, except in the south-west, where there were a few small farm lands. The greater part of the state during the south part of this area for about 60 miles along the southern boundary was a part of the great hardwood forest of the Ohio Basin with woods varying with soil and drainage: on the drier gravel lands were small forests consisting of oak, ash, hickory, maple, birch, elm, willow, hazel, alder, shrub maple, birch, hawthorn, dogwood, elderberry, viburnum and snowberry. Yews are common in the north, and dwarf juniper in the south. In 1900 the woodland area, including small stands estimated, numbered about 321,000,000 ft. in the south-west. The estimated total number of trees is 1,806,767; nearly one-half these are hemlock, among the mineral products is copper; there are about twenty copper mines in Keweenaw peninsula and its vicinity. The Calumet and Hecla mine, in the central part of that peninsula, is probably the most profitable copper mine in the world; up to 1909 it had paid

Soil.—The soil of south-west and south-east Michigan is for the most part a dark clay loam or muck; in the north central part of the lower peninsula it is a light sandy loam, along the Huron shore it is heavy with blue clay, in the mining districts of the north-west the soil is usually either barren or very thinly covered; and elsewhere in the state the soil is generally rich in a variety of mineral elements, and varies chiefly in the proportions of vegetable loam, sand or gravel, and clay.

The average temperature of the entire lower peninsula is considerably influenced by the lakes, yet, the prevailing winds being westerly, it is in the west portion of that peninsula that the moderation is greatest, both the summer and winter isotherms being there deflected more than half the length of the peninsula. On the other hand, the eastern portion of the state, especially the northern, westerly, the lakes have little effect on the temperature there, and, while in the south-west the extremes are not great, in the rest of the state they have ranged within two years from 104° F. at point lookout in August and 1#F. at Alpena in January. The range of temperature in the state July is invariably the warmest month, February the coldest, the mean annual precipitation is about 45 in., slightly more than one-half of it falls during the five growing months from May to October; the rain is evenly distributed over all parts of the state, but the snow is exceptionally heavy along the north shore of the Great Lakes. Productions.—Of the total land surface of the state in 1900 48% was in farms and 62% in (in 1904, 66.9% of the farm land was improved; the total number of farms was 203,261 (in 1904, 189,167), of which 143,688 contained less than 100 acres, 54,556 others contained less than 250 acres, and 136 contained 1000 acres or more, the average size being 86.4 acres. In 1907 the state contained 91,576,000 acres. In 1882, 168,814 were operated by the owners (in 1904, 161,037 by owners and 914 by managers), 22,482 (in 1904, 19,925) by share tenants, 9731 (in 1904, 7658) by cash tenants, and 310,426 of the inhabitants were wage laborers. The total number of horses in 1907 was 5,452,000 bushels; the hay crop, 3,249,000 tons; oats, 39,534,000 bushels; barley, 1,496,000 bushels; wheat, 12,731,000 bushels; and Indian corn 57,190,000 bushels. Of livestock, sheep are the most numerous, and in 1905 there were 5,950,000 sheep; in 1907 there were 1,806,767 hogs. The number of wheat at 1907 was 1,806,767 ($49,000 dairy cows). The number of hogs was 1,386,000, and of horses 704,000. Michigan produces the bulk of the peppermint crop of the United States. Potatoes are grown in large quantities in the northern counties.

Barley and buckwheat are grown chiefly in the east part of the lower peninsula south of Saginaw Bay. Potatoes are grown in considerable quantities in the northern counties, especially in Grand Traverse and Washtenaw counties. Barley is grown as far south as Jackson and Kalamazoo counties. Among the products of the great agricultural counties are the peppermint district is in the south-west corner of the state.; and market gardening is an important industry both in the south-west and in the south-east counties. All the principal fruits grown in the state are in the south-west, particularly in Berrien, the corner county.

The fresh-water fish caught in the Great Lakes by residents in Michigan exceed in value those caught by residents of other states, and in 1907 the catch was valued at $1,806,767. Nearly one-half these are smallmouthed, among the mineral products is copper; there are about twenty copper mines in Keweenaw peninsula and its vicinity. The Calumet and Hecla mine, in the central part of that peninsula, is probably the most profitable copper mine in the world; up to 1909 it had paid
about $167,850,000 in dividends. Copper mining in the state began about the same time as iron mining, and the quantity mined increased from 12 long tons in 1845 to 102,543 in 1906 (in 1907, 97,175 long tons). From 1847 to 1887 the product of Michigan exceeded that of all other states, except Ag to 1883 copper, and for more than one-half of all of the states, but after 1887 (except in 1891) more of that mineral was mined in Montana than in Michigan, and in 1906 and in 1907 the yield in both Arizona and Montana was greater. Field ores are found in Gogebic County, covering an area of over 10,000 sq. m. in the central portion of the lower peninsula; but its quality is inferior. The mining of coal began in Jackson county in 1835 and there was a slow increase in the output until 1882 (153,339 short tons); then there was a tendency to decrease until 1887. In 1895 the output increased as much as 58,000 short tons to 203,858 short tons in 1907. The principal mines are in Saginaw, Bay, Eaton, Jackson, Huron and Shiawassee counties. Salt wells are numerous in the middle and south-east sections of the state; and in 1897 there were 15 salt wells which produced 77,000 short tons. Manufacturing.—During the period from 1890 to 1906, the manufacturing value of the products of this state has increased from $12,469,532 in 1890 to $319,691,856, in 1906. During the same period the manufacturing value of these products increased by 2,420,982, or 151,915 (35-1%) in 1900, and to $5,951,647 (35-1%) in 1900, and to $5,951,647 in 1904, this decrease being due to the fact that the large quantities of raw material (both hard wood and pine) formerly found in the forests of Michigan had become so far depleted that the manufacture of such materials has been transferred to the west and from Canada. The value of the products of the furniture factories and of the planing mills, nevertheless, has steadily increased; that of the furniture factories (of which Grand Rapids is the leading center not only in Michigan but in the United States) has risen from $16,709,025 in 1890 to $16,614,906 in 1900 and $18,421,735 in 1904, and that of the planing mills from $10,007,603 in 1890 to $12,469,532 in 1900 and $14,375,676 in 1904. The total value of the lumber and timber products, the furniture products, and the planing-mill products amounted in 1900 to $50,999,685; the value of those manufactures based upon minerals mined or quarried amounted in the same year to 883,709,300.

Another important class of manufactures is that based on agricultural products. The value of agricultural products was $2,143,547 in 1900, and $26,912,027 in 1904; that of food preparations, for which Battle Creek is noted, to $1,891,516 in 1900 and $6,753,699 in 1904; that of agricultural implements to $6,330,358 in 1900 and $9,878,230 in 1904; and of malt liquors to $5,296,625 in 1900 and $6,999,251 in 1904. Among other manufactures in which the state ranks high and in which there was a large increase in value during the same period is that of leather, carriages and wagons, chemicals, paper and wood pulp and beet sugar. In 1904 Michigan manufactured automobiles valued at $6,876,708.

The ten leading manufacturing centres are, in the order of the value of their products, Battle Creek, Grand Rapids, Kalamazoo, Battle Creek, Saginaw, Jackson, Lapeer, Saginaw, City and Port Huron, all in the south half of the lower peninsula.

Communications.—The building of railways in Michigan began in 1850. Little progress was made in 1857 when the state began the construction of three railways, and in 1880, roads and two canals across the south half of the lower peninsula. The Michigan Central was completed from Detroit to Ypsilanti in January 1838, a portion of the Michigan Southern was in operation in November 1840, and the Illinois Central reached Chicago in 1850. The Saginaw and the two canals. By 1846, however, the state had proved itself incompetent to carry on the work and sold its interests to private companies. In 1850 there were 342 m. completed, and from then until 1890 the building of railways continued. The main railway building in Michigan was in the decade from 1880 to 1890, when the mileage was increased to 7106-684. By the close of 1892 it had further increased to 8629-35. The principal lines are: the Michigan Central, the Pere Marquette, the Lake Shore & Michigan Southern, the Grand Rapids & Indiana, the Grand Trunk, the Chicago & North-Western, the Duluth South Shore & Atlantic, the Minneapolis, St. Paul & Sault Ste. Marie, and the Chicago, Milwaukee & St Paul. A board of railway commissioners, which in 1857 was appointed on the recommendation of the legislature (who was the creation of 1873) hears complaints, has power to issue various orders and permits of minor importance to railway companies, and reports annually to the legislature. The legislature is empowered to approve or disapprove proposed expenditures for railways and express companies. Besides railway communication Michigan has a coast line of about 1,600 m., along which vessels of 2000 tons can sail and find several good harbours, the water communication extending to the Lake Huron, and the St. Lawrence, the Great Lakes, the Michigan and other canals, among which are the Sault Ste. Marie, which passes the rapids of St Mary’s River; the St Clair Flats, at the north end of Lake St Clair, by which a deeper channel is made through shoals; the Portage Lake, in the copper district; and which connects that lake with Lake Superior. The state undertook to construct that at Sault Ste. Marie in 1837 and little had been accomplished in 1835 when the national government granted 750,000 acres of land in the state to the uptowners, and in 1880 the canal was completed. It has besides construction of the two canals, the St. Lawrence-Michigan, the Bay of Green Bay, the Chicago, Milwaukee & St Paul and the Michigan Central.”

Population.—The population of Michigan in 1850 was 1,636,937; in 1860 it was 2,093,889, an increase of 27-6% within the decade; in 1890 it was 4,249,982, a further increase of 15-6% and in 1910, according to the preliminary returns of the U.S. census, it was 2,810,173. Of the total population in 1900, 2,508,503 or 99-97% were whites, 15,851 were negroes, 6354 were Indians, 240 were Chinese, and 9 were Japanese. 1,879,399 or 77-6% were native born and 414,639 were foreign-born, 114,589 of the foreign-born being natives of Canada (311,915 English; 324,839 French); 13,439 of Germany, 43,839 of England, and 30,456 of Holland. In 1906 928,479 citizens of different denominations were reported: of these 492,135 were Roman Catholics, 128,675 Methodists, 103,803 Lutherans, 50,136 Baptists, 37,900 Presbyterians, 28,345 members of Reformed bodies, and 66,349 members of the Protestant Episcopal Church. In 1900 39-3% of the total population lived in places having at least 2500 inhabitants.

Administration.—The constitution under which Michigan is now governed was first adopted in 1835, when it was felt that the powers which the first one, that of 1835, conferred upon the executive and the legislature were too unrestricted. In 1908 it was revised, and many changes were made.

The constitution admits of amendment by an affirmative vote of the majority of the entire electorate. The amendment followed at the next succeeding spring or autumn election by an affirmative vote of a majority of the electorate voting upon the question; or an amendment may be proposed by an initiative petition signed by more than 20% of the total number of electors who voted for secretary of state at the preceding election, and an amendment (unless disapproved by a majority vote in a joint meeting of the two houses of the legislature) is submitted to popular vote.
vote at the next election and comes into effect only if it receives a favourable majority of the popular vote. Amendments suggested by the legislature have been frequently adopted, and one, adopted in 1821, provided that the question of a general revision of the constitution shall be submitted to a popular vote once every sixteen years and at such other times as may be provided by law. When this question was submitted for the first time, in 1866, the vote was to revise; but the revision prepared by a convention called for the purpose was rejected at the polls. The revision by the constitutional convention of 1877-1878 was adopted by popular vote in 1898.

In its present form the constitution confers suffrage upon every male citizen of the United States who is twenty-one years of age or over and has resided in the state six months and in his township or ward twenty days immediately preceding an election; and any woman may vote in an election involving the direct expenditure of public money or the issue of bonds if she have the qualifications of male electors and if she have property assessed for taxes in any part of the district or territory affected by the election in question. At the head of the executive department is the governor, who is elected for two years, and who as the time of his election must be at least thirty years of age and must have been for five years a citizen of the United States, and for the two years immediately preceding a resident of the state. A governor whose term has expired is eligible to succeed himself to the same office in the same manner and for the same qualifications are prescribed, is elected at the same time for the same term.

Under the first constitution the secretary of state, treasurer, auditor-general, attorney-general, commissioner of the land office, superintendent of public instruction and the judges were all appointed by the governor, but under the present one they are elected and only minor officers are appointed. In 1833 the legislature created a board of four members to be appointed by the governor, one of whom must be a physician, another an attorney, and made it its duty to investigate the case of every convicts for whom a petition for pardon is received and then report and recommend to the governor what it deems expedient. The governor’s salary is fixed by the revised constitution of 1908 at $3000 a year. The lieutenant-governor succeeds the governor in case of vacancy, and next in order of succession comes the secretary of state.

The legislature, consisting of a Senate of 32 members, and a House of Representatives of 100 members (according to the constitution not less than 64 and not more than 100, members of the Senate must be elected by a majority of the House of Representatives), and representatives are elected for a term of two years by single districts, except that a township or city which is entitled by its population to more than one representative elects its representatives on a general ticket. Beginning in 1913 and at each subsequent tenth year, the legislature, under the revised constitution of 1908, rearranges the senatorial districts and reapportions the representatives among the counties and districts, using as a basis the returns of the next preceding decennial census; the taking of a state census between the decennial periods is discontinued.

No bill can pass either house except by an affirmative vote of a majority of the members elected to that house, and on its third reading no bill shall be passed unless two-thirds of all members thereof be present and it shall have passed in the same form by both houses of the legislature. All bills shall be enrolled by the governor within a period of ten days; no bill may be passed at a special session on any subject not expressly stated in the governor’s proclamation or submitted by special message. The governor has ten days (Sundays not being counted) in which to sign his veto of an act, which may be applied to any item or items of any bill making appropriations of money and embracing distinct items), and an affirmative vote in each house of two-thirds of the members elected is required to pass any bill over his veto. Under the revised constitution of 1908 any bill passed by the legislature and approved by the governor, except appropriation bills, may be referred by the legislature to the qualified electors, and no bill so referred shall become law unless approved by a majority of the electors voting thereon; no local legislative act, passed by the legislature, takes effect until it is approved by a majority vote of the electors in the affected district.

The administration of justice is entrusted to a supreme court, a continually increasing number of circuit courts (thirty-eight in 1909), one probate court in each county, and not exceeding four justices of the peace in each township. The supreme court is composed of one chief justice and seven associate justices, all elected for a term of ten years, not more than two retiring every two years; it holds four sessions annually, exercises a general control over the inferior courts, may issue, hear and determine any of the more important writs, and has appellate jurisdiction only in all other important cases. There is only one circuit court judge for a circuit, unless the legislature provides for the election of more; the term of office is six years. Circuit court judges have original jurisdiction in most matters civil and criminal, hear appeals from the lower courts, and must hold at least four sessions annually in each county of the circuit. Each county elects a judge of probate for a term of four years; he has original concurrent jurisdiction with the circuit court in matters of probate, and has original jurisdiction in all cases of juvenile delinquents and dependents. The legislature may provide for the election of more than one judge of probate in a county with more than 100,000 inhabitants. Justices of the peace are elected by the townships for a term of four years—there are not more than four in each township; in civil matters they have exclusive jurisdiction of cases in which the demand does not exceed $75 and concurrent jurisdiction with the circuit courts in contract cases in which the demand does not exceed $300.

For purposes of local government the state is divided into eighty-three counties, each of which is in turn divided regularly by N. and S. and E. and W. lines into several townships. In the more sparsely inhabited counties of the upper peninsula and in the N.E. section of the lower peninsula the townships are much larger than in other parts of the state. The officers of the township are a supervisor, clerk, treasurer, highway-commissioner, one overseer of highways for each highway district, a justice of the peace, and not more than four constables, all of whom are elected at the annual township meeting in April. The supervisor, two of the justices of the peace and the clerk constitute the township board, whose duty it is to settle claims against the township, audit accounts, and publish annually an itemized statement of receipts and disbursements. The supervisor is also the township assessor, and the several township supervisors constitute the county board of supervisors. There are also county officers provided for by special laws. Cities and boroughs, townships, and villages, authorize townships to borrow money with which to build or repair bridges, are entrusted with the care and management of the property and business of the county, and may borrow or raise by tax what is necessary to meet the more common expenses of the county. Other county officers are a treasurer, clerk, sheriff, register of deeds, attorney, surveyor and two coroners, each elected for a term of two years, a school commissioner elected for a term of four years, and one or more notaries public appointed by the governor.

Under the revised constitution of 1908 the former classification of cities into four classes and the practice of granting special charters were abolished, and the legislature is required to provide by general laws for the incorporation of cities and villages; “such general laws shall limit their rate of taxation for municipal purposes and restrict their powers of borrowing money and contracting debts.” Cities and villages are permitted upon authorization by the affirmative vote of three-fifths of the voters voting on the question—to own and operate, for the convenience of the public and in the exercise of their corporate limits, public utilities for supplying gas, water, light, heat, power and transportation, and to sell and deliver, outside their corporate limits, water, heat, power and light to an amount not more than one-fourth that furnished by them in each case within their corporate limits; but no city or village of less than 25,000 inhabitants may own or operate transportation facilities. Under the revision of 1908 corporate franchises cannot be granted for a longer term than thirty years.

Law.—A wife in Michigan has the same right to her property acquired either before or after marriage as she would have if single, except that she cannot under ordinary circumstances give, grant or
sell it to another without her husband's consent. Grounds for a divorce are adultery, physical incapacity at the time of marriage, sentence to imprisonment for three years or more, desertion for two years, habitual drunkenness, extreme cruelty, or, in case of the wife, refusal of the husband to provide for her maintenance when sufficiently able to do so; but in case the parties were married outside of Michigan the party seeking the divorce must reside within the state at least one year before petitioning for the same. An insolvent debtor is not entitled to retain for himself a house thereon, or a house and lot in a city or village not exceeding $1500 in value, together with not less than $500 of his personal property—is exempt from execution. For several years previous to 1876 a clause of the constitution prohibited the sale of intoxicating liquors within three miles of the legislature. Since 1887 the prohibition has been left to the option of each of the several counties. A state court of mediation and arbitration, consisting of three members appointed by the legislature, arranges disputes with the consent of the parties. The legislature, in 1889, into inquire into the cause of grievances threatening or resulting in any strike or lock-out and to endeavour to effect a settlement.

Charitable and Penal Institutions.—The state supports the Michigan Asylum for the Insane (opened 1859), at Kalamazoo; the Eastern Michigan Asylum for the Insane (opened 1878), at Pontiac; the Northern Michigan Asylum for the Insane (opened 1885), at Traverse City; the Michigan—Asylum for the Dangerous and Criminal Insane (established 1865), at Ionia; the Upper Peninsula Hospital for the Insane, at Munising; a Psychopathic Hospital (established 1907), at Ann Arbor; a State Sanatorium (established 1905), at Howell; the Michigan State Prison (established 1839), at Jackson; the Michigan Penitentiary (established 1839), at Lansing; the Court of Correction and Branch Prison (established 1885), at Marquette; the Industrial School for Boys, at Lansing; the Industrial Home for Girls (established 1879), near Adrian; the State Public School (opened 1829), at Coldwater, a home for the education of dependent children until homes in families can be found for them; the School for the Deaf (established 1854), at Flint; the School for the Blind, at Lansing; an Employment Institution for the Blind (established 1893), at Saginaw; the Home for the Feeble Minded and Insane (established 1863), at Lapeer; and the Michigan Soldiers' Home (established 1885), at Grand Rapids. Each of these institutions is under the control of a board of three or more members appointed by the governor, with the approval of the Senate. In case of the death, resignation, or removal of any member of the board, at the option of the remaining members the board may appoint a successor. One of the members of the board is the State Board of Corrections and Charities, consisting of the governor and four other members appointed by him, with the approval of the Senate, for a term of years, one retiring annually. This board is required to visit the institutions at least once a year to ascertain its condition and needs, and all proposed appropriations for their support, plans of buildings, proposed systems of sewage, ventilation and heating must be submitted to it.

Education.—Michigan was a pioneer state in creating the American educational system; she began the organization of it at the time of her admission into the Union in 1837, and has since been noted for the high standard of her schools. Each township operating under the District Act has two school inspectors—one being elected at each town meeting for a term of two years who with the township clerk constitute the township board of school inspectors, and to this board is given authority to divide the township into school districts and to exercise a general supervision over the several schools within their jurisdiction; a township may be organized as a single district, called a “township unit district.” The qualified electors of each district having an ungraded school elect a moderator, a director and a treasurer—one at each annual school meeting—for a term of three years, who constitute the district school board, and this board is entrusted with ample power for directing the affairs of the school. In a district having more than 100 children of school age a graded school under the control of five trustees is formed whenever two-thirds of the electors vote for it at a town meeting, and the trustees of a graded school are elected by the qualified electors of that district. The high school, when established, may be made, and secretary of the state board of education, and a member, with the power to vote, of all other boards having control of public instruction in any state institution. In every district having as many as 800 children between the ages of five and twenty the state requires that the school be taught not less than nine months a year; and a compulsory education law requires the attendance of all children between the ages of eight and fifteen for four months each year, in cities all between the same ages for the full school year, and between the ages of seven and sixteen if found frequenting public places without lawful occupation.

The higher state institutions of learning consist of a university, to which graduates of high schools on an accredited list are admitted without examination, four normal schools, an agricultural college, and a school of mines. The university (at Ann Arbor) was established in 1837, and is under the control of a board of regents elected by the people for a term of years, two every two years; the president of the institution and the superintendent of public instruction are members of the board but without the right to vote. The state normal schools which the Michigan State Normal College at Ypsilanti (organized in 1849); the Central Michigan Normal School at Mount Pleasant (established in 1852); the Northern Michigan Normal School at Marquette (established in 1899); and the Western Normal School at Kalamazoo (established in 1906) are under the state board of education, which consists of the state superintendent of public instruction and three other members elected, one every two years, for a term of six years. The agricultural college, at East Lansing, is a continuation of the University of Michigan (established in 1857) and is supported by an annual grant from the state to the amount of $35,000, and the state pays the unremitted surplus of the college account. The college of mines, at Houghton, was established in 1880 and is and is under the control of a board of six members appointed by the governor with the approval of the Senate, two every two years. The college of mines, at Houghton, was established in 1880 and is under the control of a board of six members appointed by the governor with the approval of the Senate, two every two years. The college of mines, at Houghton, was established in 1880 and is under the control of a board of six members appointed by the governor with the approval of the Senate, two every two years. the last decade of the century. The present constitution (as revised in 1908) forbids the contraction of a state debt exceeding $250,000 except for repelling an invasion or suppressing an insurrection, and the borrowing power of the minor civil divisions is restricted by a general law.

The early experience of the state with banks was scarcely less serious than that with public improvements. Although there were already fifteen banks in the state in 1837 yet the cry against monopoly was so loud that year as to lead to a law whereby any ten or more freeholders might establish a bank with a capital of not less than fifty thousand nor more than three hundred thousand dollars and begin business as soon as 30% of the capital was paid in specie. Only a few provisions were made, and those inactional, for the protection of the public: later in the same year the legislature passed an act for the suspension of specie payments which was approved on the 6th of May 1838. The general operation of this law was held in suspense. On the 1st of July, 1838, the bank of that name had out of existence by 1839, and in 1844 the bank of 1837 was declared unconstitutional. Profiting by this experience, the framers of the constitution of 1850 inserted a proviso in that document whereby no general banking law can have effect until it has been submitted to the people and has been approved by a majority of the votes cast on the question. This provision is included in the revised constitution adopted in 1908, with an additional proviso that any amendment shall be made to any banking law unless it shall receive an affirmative two-thirds vote of both branches of the legislature. The present banking law provides that the capital stock of a state bank shall be not less than $20,000 in a city, not less than $50,000 in a town, not less than $500 in a city of not more than 5000, not less than $5,000 in a city of between 5000 and 20,000, not less than $10,000 in a city of between 20,000 and 100,000, and not less than $250,000 in all larger cities. Commercial banks are allowed to keep on hand not less than 25% of their total deposits. Every stockholder in a bank is made individually liable to the amount of his stock at its par value in addition to the said stock. And all banks are subject to the inspection of the commissioner of the state bank department, who is appointed by the governor with the approval of the Senate for a term of four years.

History.—From 1613 until 1766 the territory now within the borders of Michigan formed a part of New France, and the first Europeans to found missions and settlements within those borders were Frenchmen. Two Jesuits, Raymbault and Jogues, visited the site of Sault Sainte Marie as early as 1641 for the conversion of the Chippewas; in 1668 Marquette founded there the first permanent settlement within the state; three years later he had founded a mission among the Ottawas, at Michilimackinac; La Salle built a fort at the mouth of the Saint Joseph in 1679; and in 1701 Cadillac founded Detroit as an important point for the French control of the fur trade. But the missionaries were not interested in the settlement of the country by Europeans, the fur traders were generally opposed to it, there was bitter strife between the missionaries and Cadillac, and the French system of absolutism in government and monopoly in trade were further obstacles to progress. Even Detroit was so expensive to the government of the mother country that there was occasional talk of abandoning it; and so during the last fifty-nine years that Michigan was a part of New France there were no new settlements, and little if any growth in those already established. During the last war between the English and the French in America the Michigan settlements passed into the possession of the English. Detroit in 1766 and the others in 1768, but not the Michilimackinac. The white inhabitants, still mostly French, were subjected to an English rule that until the Quebec Act of 1774 was chiefly military, and as a consequence many of the more thrifty sought homes elsewhere, and the Indians, most of whom had been allies of the French, were so ill-treated, both by the officers and traders, that under Pontiac, chief of the Ottawas, a simultaneous attack on the English posts was planned. Detroit was besieged for five months and both Michilimackinac and Saint Joseph were taken. Moreover, the English policy, which first of all was concerned with the profits of trade and manufacture, gave little more encouragement to the settlement of this section of the country than did the French. By the Treaty of Paris, in 1783, which concluded the American War of Independence, the title to what is now Michigan passed to the United States, and in 1817 this region became a part of the North-West Territory; but it was not until 1818 that Detroit and Mackinac (Michilimackinac), in accordance with Jay's Treaty of 1794, were surrendered by Great Britain. In 1800, on the division of the North-West Territory, the west portion of Michigan became a part of the newly-established Indiana Territory, into which the entire area of the present state was embodied in 1802, when Ohio was admitted to the Union; and finally, in 1805, Michigan Territory was organized, its south boundary being then described as a line drawn east from the south extremity of Lake Michigan until it intersected Lake Erie, and its west boundary a line drawn from the same starting point through the middle of Lake Michigan to its north extremity and then due north to the north boundary of the United States. In 1812, during the second war between Great Britain and the United States, General William Hull, first governor of the Territory, although not greatly outnumbered, surrendered Detroit to the British without a struggle; in the same year also Mackinac was taken and Michigan again passed under British rule. This rule was of short duration, however, for soon after Commodore Oliver H. Perry's victory on Lake Erie, in September of the next year, Detroit and the rest of Michigan except Mackinac, which was not recaptured until July 1815, were again taken into the possession of the United States. Up to this time the Territory had still remained for the most part a wilderness in which the fur trade reaped the largest profits, its few small settlements being confined to the borders; and the inaccurate reports of the surveyors sent out by the national government described the interior as a vast swamp with only here and there a little land fit for cultivation. The large number of hostile Indians was also a factor in making the Territory unattractive. But during the efficient administration of Lewis Cass, governor of the Territory from 1813 to 1831, the interference of the British was checked and many of the Indians were removed to the west of the Mississippi; printing presses, established during the same period at Detroit, Ann Arbor, Monroe and Pontiac, became largely instrumental in making the country better known; the first steamboat, the "Walk-in-the-Water," appeared at Detroit in 1818; the Erie canal was opened in 1825; by 1830 a daily boat line was running between Detroit and Buffalo, and the population of Michigan, which was only 4762 in 1810 and 8896 in 1820, increased to 31,639 in 1830 and 212,267 in 1840. In 1819 the Territory had been empowered to send a delegate to Congress. By 1832 the question of admission into the Union had arisen, and in 1835 a convention was called in Detroit, a constitution was framed in May, that constitution was adopted by popular vote in October, state officers were elected, and application for admission was made; but a dispute with Ohio over the boundary between the two caused a delay in the admission by Congress until early in the year 1837. Although the ordinance creating the North-West Territory fixed the boundary line as claimed by Michigan, yet that line was found to be farther south than was at the time expected and when the constitution of Ohio was adopted it was accompanied with a proviso designed to secure to that state a north boundary line where it had not been a factor in the dispute. The territory between the two proposed lines was unquestionably of greater economic importance to Ohio than to Michigan, and, besides, at this particular time there were forcible political reasons for not offending the older state. The consequence was that after the bloodless "war" between the two states for the possession of Toledo, Congress settled the dispute in Ohio's favour and gave to Michigan the territory since known as the upper peninsula. The boundaries as fixed by Congress were rejected by a convention which met on the 4th of September at Ann Arbor, but they were accepted by the convention of the Jackson party, which met, also at Ann Arbor, on the 6th of December; the action of this latter convention was considered authoritative by Congress, which admitted Michigan into the Union as a state on the 26th of January 1837. Since admission into the Union the more interesting experiences of the state have been with internal improvements and with banking, which together resulted in serious financial distress; in the utilization of its natural resources, which have been a vast source of
wealth; and in the development of its educational system, in which the state has exerted a large influence throughout the Union. From the beginning of its government under its first constitution, in 1835 until 1835 Michigan had a Democratic administration with the exception of the years 1840-1844, when opposition to the financial measures of the democrats placed the Whigs in power. But it was in Michigan that the Republican party received its first official recognition, at a state convention held at Jackson on the 6th of July 1857, and from the beginning of the following year the administration has been Republican with the exception of two terms from 1883 to 1885, and from 1891 to 1893, when it was again Democratic.

AUTHORITIES.—The publications of the Michigan Geological Survey (Detroit, Lansing and New York, 1832 seq.) deal largely with the mineral resources of the state, and for a time under the same editor, Alexander Kinsley, Michigan: Being Condensed Popular Sketches of the Topography, Climate and Geology of the State (1873), is in large measure restricted to the state. W. J. Beal and C. F. Wheeler, Michigan Flora of the State (1876), giving the results of an extensive botanical survey of the state, is a subject. See also the Twelfth Census of the United States (Washington, 1901-1902); Silas Farmer, Michigan Book: A State Cyclopedia with Sectional County Maps (Detroit, 1901); Bela Hubbard, Memorials of a Half Century (New York, 1887), a well written account observed chiefly upon scenery, fauna, flora and climate; Webster Cook, Michigan: its History and Government (New York, 1905), written primarily for use in schools and containing a reference bibliography; A. C. McLaughlin, History of Higher Education in Michigan, in Circulants of Information of the United States Bureau of Education (Washington, 1891), being an account of the origin of the public school system and an individual account of each higher institution; Smith, Historical Sketch of Michigan: A History and Descrip- tion (Boston, 1865), a critical but popular narrative by an eminent jurist; J. V. Campbell, Outlines of the Political History of Michigan (Detroit, 1876), also by a jurist of the state; Henry M. Utey and Byron M. Cutcheon, Michigan as a Province, Territorial and State (4 vols., New York, 1906); Michigan Pioneer and Historical Society, Historical Collections: Collections and Researches (Lansing, 1877 seq.); and Publications of the Michigan Political Science Association (Ann Arbor, 1893).

MICHIGAN, LAKE, the only one of the great lakes of North America wholly within the boundaries of the United States, and the second largest body of fresh water in the world. It lies S. of Lake Superior, and W. of Lake Huron, between 41° 27' and 46° 05' N. and 85° 45' and 88° W., is bounded on the N. and E. by the state of Michigan, on the W. by Wisconsin, while Illinois and Indiana touch its S. end. It is 320 m. long, and has an average width of 65 m. The maximum depth recorded by the United States Lake Survey is 870 ft.; the mean level of the surface is 581 ft. above sea-level, being the same as that of Lake Huron and 21 ft. below that of Lake Superior. Its area is 22,400 sq. m., and it has a basin 68,100 sq. m. in area.

The shores of Lake Michigan are generally low and sandy, and the land slopes gradually to the water. The northern shore of the lake is irregular and more rugged and picturesque than the other shores, the summit of the highest peak being about 1400 ft. above the sea. On the eastern side are numerous sand hills, formed by the wind into innumerable fantastic shapes, sometimes covered with stunted trees and scanty vegetation, but usually bare and rising to heights of from 150 to 250 ft. The south-western shore is generally low, with sand hills covered with shrivelled pines and bur oaks. Along the western shore woods and prairies alternate, interspersed with a few high peaks. The cliffs on the east shore of Green Bay form a bold escarpment, and from this ridge the land slopes gradually to the lake. With the exception of Green and Traverse bays, Lake Michigan has few indentations of the coast line, and except at the north end it is free from islands. The waters near shore are shoal, and as there are few harbours of refuge of easy access navigation is dangerous in heavy storms. Around the lake the climate is equable, for, though the winter is cold and the summer hot, the lakes of the water modify the extremes, the mean temperature varying from 40° to 54° F. The average annual rainfall is 33 in. The finest agricultural land in the United States is near the lake, and there is an immense trade in all grains, fruits, livestock and lumber, and in products such as flour, pork, hides, leather goods, furniture, &c. Rich lead and copper mines abound, as also salt, iron and coal. Abundant water power promotes manufactures of all kinds. Beer and distilled liquors are largely manufactured, and fine building stone is obtained from numerous quarries.

The lake is practically tideless, though true tidal pulsations amounting to 3 ft. in height have been observed from time to time on the eastern side. The average depth of the lake is about 8 ft., and it is subject to seasonal fluctuations, reaching a maximum in midsummer and a minimum in February, as well as to alternating cycles of years of high and low water. Standard high-water of 1838 was 3.36 ft. above mean level and standard low-water of 1895, 2-92 ft. below that datum, giving an extreme range of 6.26 ft. The northern portion of the lake only is covered with ice in winter, and ice never reaches as far south as Milwaukee. Milwaukee River remains closed on an average for one hundred days—from the beginning of December to the middle of March.

The average date of the opening and closing of navigation at the strait of Mackinac, where the ice remains longest, is the 17th of April and the 9th of January respectively. Regular lines of steamers specially equipped to meet winter conditions, most of them being car ferries, cross the lake and the strait of Mackinac all winter between the various ports.

No notable rivers flow into Lake Michigan, the largest being the Big Manistee and Muskegon on the east shore, and on the west shore the Rock river, whose delta forms a large bay which is the most important arm of the lake. The numerous harbours are mainly artificial, usually located at the mouths of streams, the improvements consisting of two parallel piers extending into the lake, protecting a dredged channel. Sand bars keep filling up the mouths of these channels, necessitating frequent dredging and extension of the breakwaters, work undertaken by the Federal government, which also maintains a most comprehensive and complete system of aids to navigation, including lighthouses and lightships, fog alarms, and other buoys, life-saving, storm signal and weather report stations.

Chicago, the principal port on the lake, is at its south-west extremity, and is remarkable for the volume of its trade, the number of vessels arriving and departing exceeding that of any port in the United States, though the tonnage is less than that of New York. It is a large railway centre, and the number and size of the grain elevators are noticeable. The port is protected by breakwaters enclosing a portion of the lake front. The level of the city above the lake being only 14 ft., much difficulty arose in draining it. A subsidence of 34 m. occurred from 1830 to 1850; in 1850 it was decided to divert the Chicago river, a small stream that flows into the lake, into the head waters of the Des Plaines river and thence through the river Joliet into the Mississippi at St Louis. The discharge of water is by law regulated so that the maximum flow shall not exceed 250,000 cub. ft.; but the whole effect upon the water level of the lakes of the withdrawal of water through this artificial outlet is receiving much attention. Milwaukee, situated on the shore of Milwaukee Bay, on the western side of the lake, is next to Chicago, this city being the only port on the lake, and has a large commerce and a harbour of refuge. Escanaba, on Little Bay de Noc (Noquetie), in the northern part of the lake, is a natural harbour and a large iron shipping port. Green Bay and Lake Michigan are connected by a canal extending from the head of the bay to the mentioned river. Lake Michigan is connected at its north-east extremity with lake Huron by the strait of Mackinac, 48 m. long, with a minimum width of 6 m.; the water is generally deep and the shoals lying near the usually travel between Michigan and Wisconsin.

MICHIGAN, UNIVERSITY OF, one of the principal educational institutions of the United States, situated at Ann Arbor, Michigan. It embraces a department of literature, science and the arts (including industry and commerce), opened in 1814, and including a graduate school, organized in 1892; a department of medicine and surgery, opened in 1850; a department of law, opened in 1850; a school of pharmacy, opened as a separate department in 1876; a homoeopathic medical college, opened in 1875; a college of dental surgery, opened in 1875; and a department of engineering, separately organized in 1895, which includes courses in marine engineering, architecture, and architectural engineering. The university was one of the first to admit women, having opened their admission in 1824. The university has received aid from the state (since 1867), and since 1900 they have constituted one-half of the student body in the department of literature, science and the arts. In 1907-1908 there were in all departments 350 instructors and 5013 students (1796 in the department of literature, science and the arts; 1354 in the department of engineering; 391 in the department of medicine and surgery; 791 in the department of law; 101 in the school of pharmacy; 82 in the homoeopathic medical college; 168 in the college of dental surgery; and 170 in the summer sessions). Besides the several main department buildings there is a library building, a museum building, several laboratories, a gymnasium for men, and a gymnasium for women. The general library in 1908 contained 172,940 volumes, 3800 pamphlets, and 3370 maps, and the several department libraries brought the total up to 222,600 volumes and 5000 pamphlets. The general museum contains large zoological collections, geological and anthropological collections, including the exhibit of the Chinese government at the New Orleans Exposition, which was given by the government to the university in 1885; there are besides several special collections in some of the laboratories. The astronomical observatory is surmounted by a movable dome in which is mounted a refracting telescope having a thirteen-inch object glass. The several laboratories are equipped for use in instruction in physics, chemistry, mineralogy, geology, zoology, psychology, botany, forestry, actuarial work, engineering, histology, physiology, hygiene, electrotherapeutics, pathology, anatomy and dentistry.

The university is governed from without by a board of eight regents elected by popular suffrage, two biennially, at the same time as the election of judges of the supreme court; from within the government is to a large extent in the hands of a university senate, in which the faculty of each department is represented. The university is maintained by a permanent endowment of $30,000, derived from the immediate grant of the Ordinance of 1787, by the proceeds of a three-eighths mill tax, and by small fees paid by the students. Its organic relation to the other public schools of the state was well established in 1870, when graduates of schools that have been examined and approved by a committee of the university should be admitted without examination; one of the most important functions of the university is to prepare students for teaching in the high schools.

The first charter for a university within what is now the state was granted by the governor and judges of the Territory of Michigan in 1817, for a "Catholepit stemuid," or University of Michigana, with a remarkable " Greek" system of nomenclature for its courses and faculties; this institution did practically no teaching. A second charter was granted in 1821, for a University of Michigan in Detroit; but little was accomplished until the admission of Michigan into the Union as a state in 1837; when by the third charter the aim was to make the institution a " Universty," and not a " College." A liberal dispensation was given the university, and the university was entrusted to a board of regents and a chancellor appointed by the governor. Branches to correspond to the German gymnasium were established in the principal towns before any money was spent on the University proper, but the question of the constitutionality of their establishment and maintenance arose, and they were soon discontinued. Plans for building at Ann Arbor were begun in 1838. The first class graduated in 1845. The department of literature, science and the arts was at first much like a New England college. For some time the prospects did not seem promising; but in 1835 a new state constitution provided that the regents should be elected, and directed them to choose a president; and it was under the administration (1835-1863) of the first incumbent of that office, Henry Philip Tappan (1805-1881), that the present broad and liberal basis was established. Although he was a Presbyterian clergyman, he endeavoured at the outset to substitute the tests of scholarship for those of religion; at the same time a scientific course was introduced, courses in pedagogy followed, and in 1878 the elective system, which has since rapidly expanded, was established. President Tappan was succeeded in 1863 by Erastus Otis Haven (1820-1885), who resigned in 1869, and was succeeded temporarily (1869-1871) by Professor Henry S. Frieze (1817-1889), and in 1871 by James Burrill Angell (b. 1829), who resigned in 1899. In 1871-1872 the German seminar method was introduced in graduate work in history, by Prof. Charles Kendall Adams (1835-1902), afterwards president of Cornell University (1885-1892) and of the University of Wisconsin (1892-1902).

See B. A. Hinsdale and I. N. Demmon, History of the University of Michigan (Ann Arbor, 1906); Elizabeth M. Farrand, History of the University of Michigan (Ann Arbor, 1885); and The Quadrant Centennial of the Presidency of James Burrill Angell (Ann Arbor, 1896).

MICHIGAN CITY, a city of Laporte county, Indiana, U.S.A., on the S.E. shore of lake Michigan, about 40 m. E. by S. of Chicago. Pop. (1890) 10,776; (1900), 14,820, of whom 3662 were foreign-born; (1910 census) 19,027. Michigan City is served by the Chicago, Indianapolis & Louisville, the Lake Erie & Western, the Michigan Central and the Pere Marquette railways, by interurban electric lines, and by several lines of lake steamships. The city contains a United States Life Saving Station and the Indiana State Prison, and is the seat of a Protestant Episcopal bishop. Its transportation connections are extensive.

1 President Angell graduated in 1849 at Brown University, where he was assistant in chemistry. He was also professor of natural law from 1853-1860; was editor of the Providence Journal in 1860-1866; was president of the University of Vermont in 1866-1871; was United States minister to China in 1880-1881, was a member of the joint commission of 1887-1888 to settle fishery disputes between the United States and Great Britain, was chairman of the international deep waterways commission in 1896, and in 1897-1898 was United States minister to Turkey.

387 MICHIGAN, UNIVERSITY OF—MICHIGAN CITY
advantages make it one of the principal commercial cities in the state. Its shipments of lumber are of special importance, and the state is a large transhipment trade in salt and iron ore. The total factory product in 1905 was valued at $6,314,226. The municipality owns and operates its water-works system. Michigan City was first settled about 1839, was incorporated as a village in 1837, and was first chartered as a city in 1867.

**MICHMASH**

**MICHMASH**—(Michmash, Mich. viii. 7.) was a very large village in the time of Eusebius. The modern Mukhmas is quite a small place.

The historical interest of Michmash is connected with the strategic importance of the position, commanding the north side of the Pass of Michmash, which made it the headquarters of the Philistines and the centre of their forays in their attempt to quell the first rising under Saul, as it was also at a later date the headquarters of Jonathan the Hasmonean (1 Macc. ix. 23). From Jerusalem to Mount Ephraim there was a good road which led almost due south from Jerusalem and descended to the ground to the west near the watershed, and avoids the Pass of Michmash altogether. But another route, the importance of which in antiquity may be judged of from Isa. x. 28 sqq., led southwards from Jerusalem to Michmash. The road was long, but easy, and Michmash descends into a very steep and rough valley, which has to be crossed before reascending to Geba. 1 At the bottom of the valley is the Pass of Michmash, a noble gorge with precipitous craggy sides. On the north the crown is crowned by a sort of plateau sloping backwards into a round-topped hill. This little plateau, about a mile east of the present village of Mukhmas, seems to have been the post of the Philistines, lying close to the centre of the insurrection, yet possessing unusually good communication with the remaining settlements in the mountains of Judah and Bethel, and at the same time commanding the routes leading down to the Jordan from Ai and from Michmash itself.

See further C. R. Conder, Tent work ii. 112 seq.; and T. K. Cheyne in Encyc. Bibl. ii. 229. (R. A. S. M.)

**MICHOACÁN, or MICHOACÁN DE CAMPO, a state of Mexico touching on the Pacific, bounded N. by Jalisco and Guanajuato, E. by Mexico and Guerrero, S. by Guerrero and the Pacific, and W. by the Pacific, Colima, and Jalisco. Pop. (1921) 935,808, chiefly Indians and mestizos. Area, 22,874 sq. m. Its territory is divided into two nearly equal parts by the eastern branch of the Sierra Madre Occidental, the northern part belonging to the great central plateau region, and the southern to an extremely broken region formed by the diverging branches of the Sierra Madre, with their wooded terraces and slopes and highly fertile valleys. The general slope of the southern part is southward to the river Balsas, or Mescalá, which forms its boundary-line with Guerrero. The narrow coastal zone on the Pacific is only 101 m. long and has no ports or towns of importance, the slopes of the Sierra Madre del Pacífico being precipitous and heavily wooded and the coast-belt sandy, hot and malarial. The Lerma, on the northern frontier, and the Balsas on the southern, are the only rivers of importance of the state, their tributaries within its boundaries being small and swift-flowing. There are several large and beautiful lakes in the state, the best known of which are Patzcuaro and Cuitzapo. Lake Chapala lies on the lower road, and Michoacán lies within the most active volcanic region of Mexico; Jorullo (4262 ft.) is near its southern line, and Colima (12,750 ft.) is northwest of it in the state of Jalisco. Earthquake shocks are numerous, and Colima was in violent eruption in 1908-1909. The highest summit in the state is Tancitaro; (13,650 ft.) The climate is for the most part temperate and healthy, but it is hot and unhealthy on the coast. Michoacán is essentially a mining region, producing gold, silver, lead and cinnabar, and having rich deposits of copper, coal, petroleum and sulphur. The natural products include fine cabinet and construction woods, rubber, fruit, palm oil and fibres. The soil of the valleys is highly fertile, and produces cereals in the higher

1 So Isa. x. 28 describes the invader as leaving his heavy baggage at Michmash before pushing on through the pass.

regions, and sugar-cane, tobacco, coffee and tropical fruits in the lower. Though the plateau region was settled soon after the arrival of the Spaniards in Mexico, there are large districts on the southern and Pacific slopes that still belong almost exclusively to the Indians. Besides Morelia, the capital and largest city, the principal towns of the state are: La Piedad (pop. 15,123), an important commercial town on the Lerma river and on the Mexican Central railway, 112 m. N.N.W. of Morelia; Zamora (10,973), 75 m. W.N.W. of Morelia; Uruapan (80,808), on the Mexican National, 55 m. S.S.W. of Morelia in a mountainous district celebrated for the fine quality of its coffee; Puruarindo (1782), a commercial and manufacturing town 40 m. N.W. of Morelia; Patzcuaro (7621), on Patzcuaro lake, with a station on the Mexican National, 7590 ft. above sea level; Sahuayo (7408), 103 m. W. by N. of Morelia near Lake Chapala; Zitacuaro (6052), 60 m. S.E. of Morelia on a branch of the Mexican National, which also passes through the mining town of Angangueo (1171) in the same district; and Tacamboro (970), 46 m. S.S.W. of Morelia in a fertile valley of the Rio de las Balsas basin.

**MICKIEWICZ, ADAM** (1798-1855), Polish poet, was born in 1798, near Nowogrodziec, in the present Russian government of Minsk, where his father, who belonged to the petty nobility, had a small property. The poet was educated at the university of Vilna; but, becoming involved in some political troubles there, he was forced to terminate his studies abruptly, and was ordered to live for a time in Russia. He had already published two small volumes of miscellaneous poetry at Vilna, which had been favourably received by the Slavonic public, and on his arrival at St. Petersburg he found himself admitted to the leading literary circles, where he was a great favourite both from his agreeable manners and his extraordinary talent of improvisation. In 1825 he visited the Crimea, which inspired a collection of sonnets in which we may admire both the elegance of the rhythm and the rich Oriental colouring. The most beautiful are The Storm, Balsheserai, and Grave of the Countess Polocka.

In 1828 appeared his Konrad Wallenrod, a narrative poem describing the battles of knights of the Teutonic order with the heathen Lithuanians. Here, under a thin veil, Mickiewicz represented the sorrowful antagonisms of races and nations which had characterized the long feud of the Russians and Poles. The objects of the poem, although evident to many, escaped the Russian censors, and it was not published until 1831, although the very motto, taken from Machiavelli, was significant: “Dovete adunque sapere come sono due generazioni da combattere . . . bisogna essere volpe e leone.” This is a striking poem and contains two beautiful lyrics. After a five years’ exile in Russia the poet obtained leave to travel; he had secretly made up his mind never to return to that country or Poland so long as it remained under the government of the Muscovites. Wending his way to Weimar, he there made the acquaintance of Goethe, who received him cordially, and, pursuing his journey through Germany, he entered Italy by the Splügen, visited Milan, Venice, and Florence, and finally took up his abode at Rome. There he wrote the third part of his poem Dejady, the subject of which is the religious commotions and religious wars. Mickiewicz’s contemporaries practised among Slavonic nations, and Pan Tadeusz, his last great poem, is his masterpiece. A graphic picture is drawn of Lithuania on the eve of Napoleon’s expedition to Russia in 1812. In this village idyll, as Brückner calls it, Mickiewicz gives us a picture of the homes of the Polish magnates, with their somewhat boisterous but very genuine hospitality. We see them before us, just as the knell of their nationalism, as Brückner says, seemed to sounding, and therefore there is something melancholy and dirge-like in the poem in spite of the pretty love story which forms the main incident. Mickiewicz turned to Lithuania with the loving eyes of an exile, and gives us some of the most delightful descriptions of Lithuanian skies and Lithuanian forests. He describes the weird sounds to be heard in the primeval woods in a country where the trees were sacred. The cloud-pictures
are equally striking. There is nothing finer in Shelley or Wordsworth.

In 1832 Mickiewicz left Rome for Paris, where his life was for some time spent in poverty and unhappiness. He had married a Polish lady, Selina Szymanowska, who became insane. In 1840 he was appointed to the newly founded chair of Slavonic languages and literature in the Collège de France, a post which he was especially qualified to fill, as he was now the chief representative of Slavonic literature. Pushkin had died in 1837. He was, however, only destined to hold it for a little more than three years, his last lecture having been given on the 28th of May 1844. His mind had become more and more disordered under the influence of religious mysticism. He had fallen under the influence of a strange fanatic named Towłanskij. His lectures became a medley of religion and politics, and thus brought him under the censure of the Government. A selection of them has been published in four volumes. They contain some good sound criticism, but the philosophical part is very defective, for Mickiewicz was no scholar, and he is obviously only well acquainted with two of the literatures, viz. Polish and Russian, the latter only till the year 1830. A very sad picture of his declining days is given in the memoirs of Herzen. At a comparatively early period the unfortunate poet exhibited all the signs of premature old age; poverty, despair and domestic affliction had wrought their work upon him. In 1840 he founded a French newspaper, La Tribune des peuples, but it only existed a year. The restoration of the French Empire seemed to kindle his hopes afresh; his last composition is said to have been a Latin ode in honour of Napoleon III. On the outbreak of the Crimean War he was sent to Constantinople to assist in raising a regiment of Poles to take service against the Russians. He died suddenly there in 1855, and his body was removed to France and buried at Montmorency. In 1900 his remains were disinterred and buried in the cathedral of Cracow, the Santa Croce of Poland, where rest, besides many of the kings, the greatest of her worthies.

Mickiewicz is held to have been the greatest Slavonic poet, with the exception of Pushkin. Unfortunately in other parts of Europe he is but little known; he writes in a very difficult language, and one which it is not the fashion to learn. There were both pathos and irony in the expression used by a Polish lady to a foreigner, "Nous avons notre Mickiewicz à nous." He is one of the best products of the so-called romantic school. The Poles had long groaned under the yoke of the classicists, and the country was full of legends and picturesque stories which only awaited the coming poet to put them into shape. Hence the great popularity among his countrymen of his ballads, each of them being connected with some national tradition. Besides Konrad Wallenrodt and Pan Tadeusz, attention may be called to the poem Grazyńska, which describes the adventures of a Lithuanian chieftainness against the Teutonic knights.

It is said by Ostrowski to have inspired the brave Emilia Plater, who was the heroine of the rebellion of 1830, and after having fought in the ranks of the insurgents, found a grave in the forests of Lithuania. A fine vigorous Oriental piece is Farys. Very good too are the odes to Youth and to the historian Lekelov; the former did much to stimulate the efforts of the Poles to shake off their Russian conquerors. It is enough to say of Mickiewicz that he has obtained the proud position of the representative poet of his country; her customs, her superstitions, her history, her struggles are reflected in his works.

It is the great voice of Poland appealing to the nations in her agony.

His son, Ladislas Mickiewicz, wrote Vie d'Adam Mickiewicz (Posen, 1890-1895, 4 vols.), also Adam Mickiewicz, sa vie et son œuvre (Paris, 1888). Translations into English (1881-1885) of Konrad Wallenrodt and Pan Tadeusz were made by Miss Biggs. See also Oeuvres littéraires de Mickiewicz, tr. by Christiane Lecoyer de la Gaume (Paris, 1845). (W. R. M.)

MICKLE, WILLIAM JULIUS (1735-1788), Scottish poet, son of the minister of Langholm, Dumfriesshire, was born on the 28th of September 1735. He was educated at the Edinburgh High School, and in his fifteenth year entered business as a brewer. His father purchased the business, and on his death William Mickie became the owner; but he neglected his affairs, devoting his time to literature, and before long became bankrupt. In 1763 he went to London, where in 1765 he published "a poem in the manner of Spenser," called the Concubine (afterwards Sir Tyrconnell); was appointed corrector to the Clarendon Press, and translated the Lusiac of Camoens into heroic couplets (specimen published 1771, whole work, 1775). So great was the repute of this translation that when Mickie—appointed secretary to Commodore Johnstone—visited Lisbon in 1779, the king of Portugal gave him a public reception. On his return to London he was appointed one of the agents responsible for the distribution of prize-money, and this employment, in addition to the sums brought him by his translation of the Lusiad, placed him in comfortable circumstances.

MICKMAC, a tribe of North American Indians of Algonquian stock. They formerly occupied all Nova Scotia, Cape Breton and Prince Edward Islands, and portions of New Brunswick, Quebec and Newfoundland. They fought on the French side in the colonial wars. They are now civilized and almost all profess Catholicism. They number some 4000 in settled communities throughout their former territory.

There is an excellent account of the Micmac Indians in J. G. Milham's New England and its Unravled Ways (1908).

MICON, a Greek painter of the middle of the fifth century B.C. He was closely associated with Polygnotus of Thasos, in conjunction with whom he adorned the Painted Stoa, at Athens, with paintings of the battle of Marathon and other battles. He also painted in the Anacreon at Athens.

MICROCLINE, a rock-forming mineral belonging to the feldspar group (see Feldspar). Like orthoclase it is a potash-feldspar with the formula KAlSi3O8, but differs from this in crystallizing in the anorthic system. The name (from Greek mykrod, small, and ALOOE, to incline) was given by A. Breithaupt in 1830, and has reference to the fact that the angle (80° 30') between the two perfect cleavages differs but little from a right angle: the species was, however, first definitely established by A. Des Cloizeaux in 1876. The crystals and cleavage masses are very like orthoclase in appearance, and the hardness (6) and specific gravity (2.56) are the same for the two minerals; there are, however, important differences in the twinning and in the optical characters. In addition to being twinned according to the same laws as orthoclase, microcline is repeatedly twinned—being called the albite-law and the pericline-law, producing a very characteristic grating or cross-hatched structure which is especially prominent when thin sections of the mineral are examined in polarized light. This lamellar structure is often on a very minute scale, sometimes so minute as to be almost indistinguishable: it has therefore been suggested that orthoclase is really a microcline in which the twin-lamellae are ultra microscopic. In a section parallel to the basal plane c (001) of a microcline crystal the lamellae do not extinguish optically parallel to the edge bc as in orthoclase, but at an angle of 15° 30'; further, the obtuse bisectrix of the optic axes in microcline is inclined to the normal of the plane b (010) at an angle of 15° 26'; Green microcline is distinctly pleochroic.

Microcline occurs, usually with orthoclase, as a constituent of pegmatites, granites and gneisses; it is rare in porphyries and is not known in volcanic rocks. A beautiful crystallized variety of a bright yellow, when colorless, is known as amazonite (q.v.). Chesterite is a variety occurring as crystals on dolomite in Chester country, Pennsylvania.

Closely allied to microcline is the anorhomic soda-potash-feldspar known as anorthoclase or natroline-microcline. Here sodium predominates over potassium and a little calcium is also often present, the formula being (Na, K) AlSi3O8. It resembles microcline in having a cleavage angle of very nearly 96°, and in the cross-hatched structure, the latter being usually very minute and giving rise to a mottled
extinction. It is the characteristic fieldspar of volcanic rocks which are rich in soda, and is typically developed in the lavas of the island of Pantelleria near Sicily and those of Kilimanjaro and Mount Kenya in East Africa: the rhomb-shaped porphyritic feldspars of the "rhombi-porphory" of southern Norway also belong here.

( L. J. S.)

MICROCOmM, a term often applied in philosophical and in general literature to man regarded as a "little world" (Gr. μικρὸς κόσμος) in opposition to the "macromos," great world, in which he lives. From the dawn of speculative thought in Greece the analogy between man and the world has been a common-place, and may be traced from Heraclitus and Empedocles, through Plato, Aristotle, the Stoics, the Schoolmen and the thinkers of the Renaissance down to the present day. Thus Lotze's comprehensive survey of mental and moral science is termed "Microcosmus," The most systematic expression of the tendency indicated by the term is the monadology of Leibniz, in which the monad is regarded as containing within its own closed sphere an expression of the universe, the typical created monad being the human soul.

MICROSCOMIC SALT, or ammonium sodium hydrogen orthophosphate, NH₄NaHPO₄. 4H₂O, so named by the alchemists because it is contained in the decomposing urine of man (the "micromelicum"). It is interesting historically as being the raw material from which Bredt prepared phosphorus, whence it is also called "salt of phosphorus." It may be obtained in large transparent crystals from a mixture of solutions of sal-ammoniac and disodium phosphate, or by saturating a solution of monosodium phosphate with ammonia. When heated to redness, it leaves a transparent glass of sodium metaphosphate, Na₃PO₄, which by borax dissolves most metallic oxides, with formation of glasses that often exhibit characteristic colours, and which may be used in the qualitative analysis of substances.

(See CHEMISTRY, § Analytical.)

MICROMETER (from Gr. μικρός, small, μέτρον, a measure), an instrument generally applied to telescopes and microscopes for measuring small angular distances with the former, or the dimensions of small objects with the latter.

Before the invention of the telescope the accuracy of astronomical observations was necessarily limited by the angle that could be distinguished by the naked eye. The angle between two objects, such as stars or the opposite limbs of the sun, was measured by directing an arm furnished with fine "sights" (in the sense of the "sights" of a rifle) first upon one of the objects and then upon the other (q.v.), or by employing an instrument having two arms, each furnished with a pair of sights, and directing one pair of sights upon one object and the second pair upon the other. The angle through which the arm was moved, or, in the latter case, the angle between the two arms, could be read off upon a finely graduated arc. With such means no very high accuracy was possible. Archimedes concluded from his measurements that the sun's diameter was greater than 27' and less than 32'; and even Tycho Brahe was so misled by his measures of the apparent diameters of the sun and moon as to conclude that a total eclipse of the sun was impossible.1 Michael Maestlin in 1579 determined the relative positions of eleven stars in the Pleiades (Historia coelestis Lucii Borelli, Augsburg, 1660), and A. Winnecke has shown (Monthly Notices R.A.S., xxxix. 146) that the probable error of these measures amounted to about 1'.

The invention of the telescope at once extended the possibilities of accuracy in astronomical measurements. The planets were shown to have visible disks, and to be attended by satellites whose distance and position angle relative to the planet it was desirable to determine. It became the essential tool of a "micrometer" for measuring the small angles which were thus for the first time rendered sensible. There is now no doubt that William Gascoigne, a young gentleman of Yorkshire, was the first inventor of the micrometer. William Crabtree, a friend of his, taking a journey to Yorkshire in 1639 to see Gascoigne, writes thus to his friend Jeremiah Horrocks. "The first thing Mr. Gascoigne showed me was a large telescope amplified and adorned with inventions of his own, whereby he can take the diameters of the sun and moon, or any small angle in the heavens or upon the earth, most exactly through the glass, to a second." The micrometer so mentioned fell into the possession of Richard Townley of Lancashire, who exhibited it at the meeting of the Royal Society held on the 25th of July 1667.

The principle of Gascoigne's micrometer is that two pointers having parallel edges at right angles to the measuring screw, are moved with opposite directions symmetrically and at right angles to the axis of the telescope. The micrometer is at zero when the two edges are brought exactly together. The edges are then separated till they are tangent to the opposite limbs of the disk of the planet to be measured, or till they respectively bisect two stars, the angle between which is to be determined. The symmetrical separation of the edges is produced and measured by a single screw; the fractions of a revolution of the screw are obtained by an index attached to one end of the screw, reading on a dial divided into 100 equal parts. The whole arrangement is elegant and ingenious. A steel cylinder (about the thickness of a goose-quill), which forms the micrometer screw, has two threads cut upon it, one-half being cut with a thread of the other, so that one thread of the screw is slanted. The cylinder box carries one of the measuring edges; the other edge is moved by the coarser part of the screw relatively to the edge attached to the box, whilst the box itself is moved relatively to the axis of the telescope. The finer thread produces an opening and closing of the edges symmetrically with respect to the telescope axis. Flamsteed, in the first volume of the Historia coelestis, has inserted a series of measurements made by Gascoigne extending from 1638 to 1643. Of the number of stars measured by him, and of the Pleiades, a few observations of the apparent diameter of the sun, others of the distance of the moon from neighbouring stars, and a great number of measurements of the diameter of the moon. Dr. John Gad (Phil. Trans. (173), p. 190) also gives results of measurements by Gascoigne of the diameters of the moon, Jupiter, Mars and Venus with his micrometer.

Delambre gives the following comparison between the results of Gascoigne's measurements of the sun's semidiameter and the computed results from modern determinations:

<table>

</tbody>
</table>

Gascoigne, from his observations, deduces the greatest variation of the apparent diameter of the sun to be 35"; according to the Connaissance des temps it amounts to 32°-3'. These results prove the enormous advance attained in accuracy by Gascoigne, and his indisputable title to the credit of inventing the micrometer.

Huygens, in his Systema Saturni (1659), describes a micrometer with which he determined the apparent diameters of the principal planets and of the sun and moon, by microscopic and variable breadth, at the focus of the telescope, and observed that "while it exactly covered the object under examination; knowing the focal length of the telescope and the width of the slit at the point observed, he thence deduced the apparent angular breadth of the object. The Marquis Malvasia in his Ephemerides (Bologna, 1662) describes a micrometer of his own invention. At the focus of his telescope he placed fine silver wires at right angles to each other, which, by their intersection, formed a network of small squares. The mutual distances of the intersecting wires he determined by counting, with the aid of a pendulum clock, the number of seconds required by an equatorial star to pass from web to web, while the telescope was adjusted so that the star ran parallel to the wires at right angles to those under investigation. In the Phil. Trans. (1669), No. 21, p. 373, Adrien Azout gives the results of some measures of the diameter of the sun and moon made by himself and his communication led to the letters of Townley and Bevis above referred to. The micrometer of Azout and Picard was provided with silk fibres or silver wires instead of the edges of Gascoigne, but one of the silk fibres remained fixed while the other was moved by a screw. It is beyond doubt that Huygens independently discovered that an object placed in the common focus of the two lenses of a Kepler telescope appears as distinct and well-defined as the

1 Grant, History of Physical Astronomy, p. 449.
2 This is an astonishing accuracy when the difficulty of the objects is considered. Few persons can see with the naked eye—much less measure—more than six stars of the Pleiades, although all the stars measured by Maestlin have been seen with the naked eye by a few individuals of exceptional powers of eyesight.

3 Delambre, Histoire de la mère de l’art, ii. 590.
4 Mécan. acad. des sciences (1717), pp. 78 seq.
image of a distant body, and the micrometers of Malavias, Auzout and Picard are the natural developments of this discovery. Gascoigne was killed at the battle of Marston Moor on the 2nd of July 1644, in the twenty-fourth year of his age, and his untimely death was doubtless the cause that delayed the publication of a discovery which anticipated, by twenty years, the combined work of Huygens, Malavias, Auzout and Picard in the same direction.

As the powers of the telescope were gradually developed, it was found that the finest hairs or filaments of silk, or the thinnest silver wires that could be drawn, were much too thick for the refined purposes of the astronomer, as they entirely obliterated the image of a star in the more powerful telescopes. To obviate this difficulty Felice Fontana of Florence (Saggio del reale cabinato di fisica e di storia naturale, 1755) first proposed the use of spider webs in micrometers, but it was not till the attention of Troughton had been directed to the subject by Rittenhouse that the idea was carried into practice.

In 1813 Wollaston proposed fine platinum wires, prepared by surrounding a platinum wire with a cylinder of silver, then winding the cylinder with silver and finally passing a fine wire through the center. The surrounding silver was then dissolved by nitric acid, and a platinum wire of extreme fineness remained. But experience soon proved the superiority of the spider web; its perfection of shape, its lightness and elasticity, have led to its universal adoption.

Beyond the introduction of the spider line it is unnecessary to mention the various steps by which the Gascoigne micrometer assumed the modern forms now in use, or to describe in detail the suggestions of Hooke, Wren, Smeaton, Cassini, Bradley, Maskelyne, Herschel, Arago, Pearson, Bessel, Struve, Dawes, &c., or the successive productions of the great artists Ramsden, Troughton, Fraunhofer, Ertel, Simms, Cooke, Grubb, Clarke and Repsold. It will be sufficient to describe those forms with which the most important work has been done, or which have survived the tests of time and experience.

Before astronomical telescopes were mounted parallactically, the measurement of position angles was seldom attempted. Indeed in those days, the difficulties attached to such measurements, and to the measurement of distances with the filar micrometer, were exceedingly great, and must have taxed to the utmost the skill and patience of the observer. Yet, the most accurate accounts of the position of the axis of the telescope when pointed to a star is always changing, so that, to follow a star with an altazimuth mounting, the observer requires to move continuously the two handles which give him the right ascension and azimuth. The most accurate measurements were comparatively crude, because of the difficulties he had to encounter from the want of a parallactic mounting. In the case of close double stars he estimated the distance in terms of the disk of the component. For the measurement of wider stars he invented his lamp-micrometer, in which the component of a double star observed with the right eye was made to coincide with two fiduciary points placed 10 ft. from the left eye. The distance of the fiduciary points was the tangential, or magnified angles subtended by the stars on the eyepiece, or to 10 ft. This angle, together with the magnifying power of the telescope gives the real angular distance of the centres of a double star. With a power of 400 the scale was a quarter of an inch for every second.

The Modern Filar Micrometer

When equatorial mountings for telescopes became more general, no filar micrometer was considered complete which was not fitted with a position circle. 1 The use of the spider line or filar micrometer became universal; the methods of illumination were improved; and micrometers with screws of previously unheard of fineness and accuracy were produced. These facilities, coupled with the wide and fascinating field of research open up by Sir William Herschel's discovery of the binary stars, greatly stimulated micrometric research which has continued unabated to the present time. A still further facility was given to the filar micrometer by the introduction of clockwork, which caused the telescope automatically to follow the diurnal motion of a star, and left the astronomer's hands entirely at liberty.

The micrometer represented in figs. 1, 2, 3 is due to Troughton. Fig. 1 is a horizontal section in the direction of the axis of the telescope. The eyepiece ab consists of two plano-convex lenses a, b, near the same focal length, and with the two convex sides facing one another. They are placed at a distance apart less than the focal length of a, so that the wires of the micrometer, which must be distinctly seen, are beyond b. This is known as Ramsden's eyepiece, having been made originally by him. The eyepiece slides into the tube cd, which slides into the brass ring eg, through two openings in which the oblong frame, containing the micrometer slides, passes. These slides are shown in fig. 2, and consist of brass forks k and l, into which the ends of the screws o and p are rigidly fitted. The slides are accurately fitted so that they have no sensible lateral shake, but yet so as to move easily in the direction of the greatest length of the micrometer box. Motion is communicated to the forks by female screws tapped in the heads m and n acting on the screws o and p respectively. Two pins g, r, which screws could round them, pass loosely through holes in the forks k, l, and keep the bearings of the heads m and n firmly pressed against the ends of the micrometer box. Thus the smallest rotation of either head communicates to the corresponding slide motion. If the screws are accurate, the amount of motion which the head is turned is graduated into equal parts of the drums u and v, so that, by estimation, the reading can easily be carried to 1/100 of a revolution. The total number of revolutions is read off by a scale attached to the side of the box, but not seen in the figure.

Two spider webs are stretched across the forks, one (t) being cemented in a fine groove cut in the inner fork k, the other (s) in a similar groove cut in the outer fork l. These grooves are simultaneously cut in situ by the maker, with the aid of an engine capable of ruling fine straight lines, so that the webs when accurately laid in the grooves are perfectly parallel. A wire s is stretched across a radius of the field of the telescope, the parallel wires being rigidly attached to the fork k. The movable web must pass the other without coming in contact with it or the fixed wire, and without rubbing on any part of the brasswork. Should either fault occur (technically called "fiddling") it is fitted. The slides are accurately fitted so that the two points in a good micrometer is that all the webs shall be nearly in the same plane as to be well in focus together under the highest powers used, and at the same time absolutely free from "fiddling." For measuring position angles a brass circle gh (fig. 3), fixed to the telescope by the screw r, has rack teeth on its circumference. The teeth of an endless screw w, which is fixed by the arm xx to the oblong box mn, gives the latter a motion of rotation round the axis of the telescope. When the point gh touches the oblong box mn, the motion is stopped; the point gh is then on the graduated circle gh of the angular rotation of the instrument.

The micrometer by Troughton, fitted to their 5 ft. equatorial telescope, is the first position micrometer constructed capable of measuring position angles to 1' of arc. So far as we can ascertain, the first telescope of large size driven by clockwork was the 9-in. equatorial made for Struve at Dorpat by Fraunhofer; it was completed in 1825. The original idea appears to be due to Claude Simon Passemant (Mem. Acad. Paris, 1746). In 1757 he presented a telescope to the king, so accurately driven by clockwork that it would follow a star all night long.
The English micrometer still retains the essential features of Troughton's original construction above described. The later English artists have somewhat changed the mode of communicating motion to the screw by attaching the screws permanently to the micrometer head and tapping each micrometer screw into place. Instead of making the shoulder of the screw a flat bronze bearing surface, they have given the screw a spherical bearing resting in a hollow cone (fig. 4). The French artists still retain Troughton's form.

Fraunhofer's Filar Micrometer. The micrometer represented in fig. 5 is the original Merz micrometer of the Cape Observatory, made for Fraunhofer's model. S is the head of the micrometer screw proper, s that of the screw moving the slide to which the so-called "fixed web" is attached, s' that of a screw which moves the eyepiece E. C is the clamp and M the slow motion in position angle L L are tubes arranged to a larger tube N; the latter fits loosely on a strong hollow cylinder which terminates in the screw V. By this screw the whole apparatus is attached to the telescope.

To use the instrument, it is well first to adjust the web moved by the screw S, so that its point of intersection with the web of the fixed web coincides with the position-web, which is parallel to the axis of the screw, shall be nearly coincident with the axis of rotation of the micrometer box. For this purpose it is only necessary to direct the telescope to some distant object, bisect that object with the movable wire, and read the number of revolutions and parts of a revolution of the screw; now reverse the micrometer box 180° and repeat the observation; the mean of the two readings will be the point required. Now direct the telescope to a star near the equator and so that the image of the star when at a considerable distance from the axis of rotation of the micrometer box, shall pass across the intersection of the two webs which mark the axis of rotation of the micrometer box. Then, as the diurnal motion causes the star-image to travel away from the axis of rotation, the micrometer box is rotated, the star-image remaining bisected, while it traverses the whole length of the position-web by the diurnal motion only. This determines the reading of the position-circle corresponding to position-angle 90° or 270°.

3 When it is remembered that the measurements of the Struves, Dombowskis, Scwefel, the Bonds, Maclaurin and of most modern European astronomers have been made with Fraunhofer or Merz micrometers it is not too much to say that fig. 5 represents the instrument with which a half of the astronomical measurements of the 19th century were made.

4 For the corrections applicable to measures of position-angle in different hour angles, on account of errors of the equatorial instrument and of refraction, see Chauvenet's Practical and Spherical Astronomy, ii. 392 and 450.

The position-angles of double stars are reckoned from north through east, the brighter star being taken as origin. To observe the position-angle of a double star it is only necessary to turn the position-web so that it shall be parallel to the line joining the centres of the components of the double star. To test this parallelism the single web must be made to bisect the images of both components simultaneously, as in fig. 6, because it is evident that if the two components of the double star are not exactly equal in magnitude there will be great tendency to systematic error if the web is placed on one side or other of the stars.

To avoid such error Dawes used double wires, not spider webs, placing the image of the stars symmetrically with respect to the wires. Other astronomers used distance-measuring webs, placed at a convenient distance apart, for position wires. This plan has the advantage of permitting easy adjustment of the web to such a distance apart as may be found most suitable for the particular observation, but has the disadvantage that it does not permit the zero of the position-circle to be determined with the same accuracy; because, whilst by means of the screw S (fig. 5) the eyepiece can be moved along a position-web parallel to the screw, the bisection of the web by a star moving by the diurnal motion at right angles to the micrometer screw can only be followed for a limited distance, viz. the field of the eyepiece. But, as the angle between the position-wires and the distance-wires is a constant, it is possible to determine that angle (always very nearly a right angle) by any independent method and employ the distance-wires as position-wires in the way described, using the position-web only to determine the instantaneous axis error.

To measure distances with the Fraunhofer micrometer, the position-circle is clamped at the true position-angle of the star, and the telescope is moved by its slow motions so that the component A of the stars bisected by the fixed wire; the other component B is then bisected by the web, which is moved by the graduated head S. Next the star B is bisected by the fixed web and A by the movable one. The difference between the two readings of S is then twice the distance A B.

The great improvement now introduced into all the best micrometers is to provide a screw S, which, not as in the Fraunhofer micrometer, moves only one of the wires, but which moves the whole micrometer box, i.e. moves both webs together, so that the star's image in the direction of the axis of the screw. Thus the fixed wire can be set exactly on star A by the screw S, while star B is simultaneously bisected by the movable wire, or vice versa, without disturbing the reading for coincidence of the wires. No one, unless he has previously worked without such an arrangement, can fully appreciate the advantage of bringing up a star by bisection moving a micrometer with a delicate screw-motion, instead of having to change the direction of the axis of the micrometer box for the purpose. When it is further remembered that the earlier telescopes were not provided with the modern slow motions in right ascension and that the Struves, in their extensive observations of double stars, were led to make frequent change of axis of rotation of the micrometer box, it is easy to understand whether more to wonder at such poor adaptation of means to ends or the patience and skill with, such means, to such results. Dawes, who employed a micrometer of the kind illustrated in figs. 1, 2, and 3, used to bolt the head of one of the screws, and the instrument was provided with a slipping piece, giving motion to the micrometer by screws acting on two slides, one in right ascension, the other in declination, so that either of the webs can be placed upon either component of a double star with the same facility. (Mem. R.A.S. xxxv. i. 9.)

The micrometer shown in fig. 8 was made by Repsold for the Cape Observatory. Fig. 6 is a representation of the same.
micrometer with the upper side of the box removed. The letters in the description refer to both figures.

S is the head of the micrometer screw, s that of the screw by which the micrometer box is moved relative to the plate $f$ (fig. 8), $s'$ that of the screw which moves the eyepiece slide. $K$ is the clamp in position-circle $P$, the slow motion screw in position-angle; $p$ is the position circle, $R$, $R'$ its two readers. The latter are in fact little microscopes carrying a vernier engraved on glass, in lieu of a filar micrometer. These verniers can be read to 4', and estimated to 0'. $D$ is the drum-head which gives the fraction of a revolution, $d$ that which gives the whole number of revolutions, $I$ is the index or pointer at which both drums are read. This index is shown in fig. 9, but only its mode of attachment (X, fig. 9) in fig. 8. The teeth of the pinion $z$, fig. 9, are cut on the axis of the micrometer screw. The drum $d$ and

its attached tooth wheel are ground to turn smoothly on the axis of the screw. The pinion $z$ and the toothed wheel $d$ are connected by an intermediate wheel and pinion $Y$; the numbers of teeth in the wheels and pinions are so proportioned that twenty-four revolutions of the micrometer screw produce one revolution of the drum and wheel $d$. The divisions of both drums are conveniently read, simultaneously, by the lens $r$; at night the lamp which illuminates the web and the position-circle also illuminates the drum-heads (see on illumination p. 385). $O$ is the web-frame (fig. 9). $P_y$ is a single rod consisting of two cylinders accurately fitting in the ends of the micrometer box, the larger cylinder being at $P$, and another which similarly fits the smaller cylinder at $y'$. A spiral spring, coiled round the cylinder $y$, resting one end on the shoulder formed by the difference of the diameters of the cylinders $P$ and $p$, is attached to the other on the inside of the webs, presses the latter continuously towards $y$. Contact of the web-frame of the micrometer with the side of the box at $y$ would therefore take place, were it not for the micrometer screw. This screw fits neatly in the end of the box at $y$, passes loosely through the web-frame at $y'$, is tapped into the frame at $y'$, and its end rests on a flat hardened surface at $y$. Rotation of the web-frame about $P_y$ is prevented by the heads of the screws at $m$; the head of the screw on the lower side of the frame reposes on the plane $y$, that on the upper side of the frame on the plane of a screw. With the weight of the slide is on one side of the screw, misfit here will have the effect of changing the reading for coincidence of the movable with the fixed web in reverse positions of the micrometer. With the Cape micrometer a systematic difference has been found in the coincidence point for head above and head below amounting to 0'. This corresponds, in the Cape instrument, with an excess of the diameters of the holes over those of the cylinders of about $1 \frac{1}{16}$th of an inch—a quantity so small as to imply good workmanship, though it involves a systematic error which is very much larger than the probable error of a single determination of the coincidence point. The obvious remedy is to make all measures on opposite sides of the fixed web before reversing in position-angle—a precaution, however, which no careful observer would neglect. In measuring differences of declination, where the stars are brought up by the diurnal motion, this precaution cannot be adopted, because it is necessary always to bisect the preceding star with the fixed web. But in $\Delta$ measures index error can be eliminated by bisecting both stars with the same web (or different webs of known interval fixed on the same frame), and not employing the fixed web at all. The discordance in zero, when known to exist, is really of no consequence, because the observations can be so arranged as to eliminate it.

The box is mounted on a strong hollow steel cylinder CC (fig. 9) by holes $s$, $s'$ in the ends of the box, which fit the cylinder closely and smoothly. The cylinder is rigidly fixed in the studs $C, C'$, and these are attached to the foundation plate $f$. The cylinder contains towards $s$ a sliding rod, and towards $s'$ a compressed spiral spring. There is thus a thrust outwards of the spring upon the hollow cap W (attached outside the box), and a thrust of the rod upon the end of the screw. If $s$ was the box related to the plate $f$, in the direction of measurement, depends therefore on the distance between the end of the screw $s$ and the fixed stud $C$. A screwing in of $s$ thus causes the box to move to the left, and vice versa. Rotation of the box round $C C'$ is prevented by downward pressure of the spring $Z$ on a projection attached to the side of the box. The amount of this pressure is regulated by the screw $z'$.

The short screw whose divided milled head is $\sigma$ shifts the zero of the micrometer by pushing, without turning, the short sliding rod whose flat end forms the point d'appui of the micrometer screw at $s$. The pitch of the screw $s$ is the same as that of the measuring screw (50 threads to the inch), and its motion can be limited by a stop to half a revolution.

The five fixed webs are attached to the table $t$, which is secured to the bottom of the box by the screws $p$. The three movable webs are attached to the projections $\lambda \lambda$ on the frame $e e$. The plane surfaces of the webs influence the accuracy of the instrument, which appears capable of receiving a finishing having almost the truth and polish of an optical surface. It seems also to take a very clean V cut, as the webs can be laid in their furrows with an astonishing ease and precision. These furrows have apparently been cut in with a very accurate instrument. The faces of webs, connected with parallelism can be detected in any of the movable webs relative to the fixed webs. Extraordinary care has evidently been bestowed in adjusting the parallelism and distance of the planes $r$ and $\lambda$, so that the movable wires shall almost, but not quite, touch the surface $t$. The varnish to fix the webs is applied, not on the surface $r$ as is usual, but on a bevel for the purpose of the webs depending on their tension to keep them in their furrows. The result is that no trace of "hiding" exists, and the movable and fixed webs come sharply together in focus with the highest powers. Under such powers the webs can be brought into apparent contact with such precision and delicacy that the uncertainty of measurement seems to lie as much in the estimation of the fraction of the division of the head as in the accuracy of the contact. It is

a convenient feature in Repsold's micrometer that the webs are very near the inner surface of the top of the box, so that the eye is not brought inconveniently close to the plate where high powers are used.

Another excellent micrometer, originally based on a model by Clark of Cambridge, Massachusetts, has been largely used by Burnham and others in America. The form, as constructed by Warner and Swasey for the 40-in. Yerkes telescope, is shown in figs. 10 and 11. Of the device, precisely as the other micrometers, is moved by the screw $s$, whilst the measuring web is independently moved by the screw $S$. The other parts of the instrument will be readily understood from the figure without further explanation. The method of counting the total number of revolutions gives more friction and is less convenient than Repsold's, and no provision seems to have been made for illuminating the micrometer head in the practical and convenient plan adopted by Repsold.

Repsold's more recent form of the spider-line micrometer (since

\footnote{The marks of varnish so applied will be seen in fig. 9.}
position-angle by the screw $K$ and slow motion in position-angle is given by the screw $p$. The small drum-head $T$ opposite the micrometer head $S$ turns a screw which acts on a short cylinder that cannot turn but can move only in the direction of the axis of the micrometer screw. The end-plane of this cylinder receives the pressure of the micrometer screw, so that by turning the small drum-head the coincidence-reading of the movable web with the fixed web can be changed, and thus any given angle can be measured with different parts of the micrometer screw in order to eliminate the effects of periodic error of the screw. The electric lamp $a$ gives illumination of the webs in a dark field, nearly in the manner described for the Cape transit circle micrometer; the intensity of illumination is regulated by a carbon-resistance controlled by the screw $b$. The lamp $c$ illuminates the drum-head and also, by reflection, the portions of the position-circle which come under the microscopes $d$ and $e$. The head $f$ is a switch which enables the observer to illuminate lamp $a$ or $c$ at pleasure. These lamps, although shown in the figure, are in reality covered so as not to shine upon the observer's eye. The illumination of the field is given by a lamp near the object glass, controlled by a switch near the micrometer.

Repsold in more recent micrometers under construction give a second motion to the eyepiece at right angles to the axis of the micrometer screw; this enables the observer to determine the zero of position-angle for his movable webs with the same accuracy as he formerly could only do for the so-called position-angle webs. Repsold also provide two insulated sliding contact rings instead of the single ring $g$, so that the electric current for illuminating the lamps does not pass through the instrument itself but may come to the micrometer from the storage battery through two insulated leads. The same firm is also constructing a micrometer in which the readings of the head are printed on a band of paper instead of being read off at the time of observation.

Instruments have been invented by Alvan Clark and Sir Howard Grubb for measuring with the spider-line micrometer angles which are larger than the field of view of the eyepiece. In both cases two eyepieces are employed, one to view each separate web. The drawback to this form of instrument is that the two webs cannot be viewed simultaneously, and therefore the observer must rely on the steadiness of rate of the clockwork and uniformity in the conditions of refraction whilst the eye is moved from one eyepiece to the other.

Clark's micrometer was exhibited at the June meeting of the Royal Astronomical Society in 1859 (Monthly Notices, R.A.S., vol. viii.). Grubb's duplex micrometer is described in the 9th edition of the Encyclopaedia Britannica. Some examples of use of the latter are given by Professor Pritchard (Mem. R.A.S. xlvii. 4-12), who estimates the accuracy attainable with the duplex micrometer as equal to that of the heliometer; but as few measures of permanent value have been made with the instrument, and those which have exhibit an accuracy far inferior to that of the heliometer, it is unnecessary to describe the instrument here in greater detail.

The Reading Micrometer-Microscope.—Micrometers used for subdividing the spaces on graduated circles and scales have, in general, only a single pair of cross-webs or parallel webs moved by a single screw. The normal form of the apparatus is shown in figs. 13 and 14. C is the objective, D the micrometer box, $E$ the graduated arc of the screw, and $F$, the milled head by which the screw $cc$ is turned, A an eyepiece sliding in a tube $B$, $aa$ (fig. 14) the slide, and $b$, $b$, the spiral springs. The focal length of the objective and the distance between the optical centre of the lens and the webs are so arranged that images of the divisions are formed in the plane of the webs, and the motion of the division of the scale is such that $cc$ corresponds with some whole number of revolutions of the screw.

There is what is technically called a "comb," inserted in the micrometer box at $A$ (fig. 14)—its upper surface being nearly in the plane of the wires. This comb does not mate in the micrometer box, and serves to indicate the whole revolution of which a fraction is read on the head. In fig. 14 a division is represented bisected by cross webs, and five revolutions of the screw correspond with one division of the scale. In all modern reading micrometers the cross webs of fig. 14 are replaced by parallel webs embracing the division (fig. 15). The means for changing the length of the tube and the distance of $C$ from the scale are omitted in the figure. These appliances are required if the "run" has to be accurately adjusted. By "run" is meant the difference between the intended whole number of screw-revolutions and the actual measures of the space between two adjacent divisions of the scale in turns of the screw. Fig. 15 is divided by the number of intended revolutions. In delicate researches two divisions of the scale should always be read, not merely for increased accuracy but to obtain the corrections for "run" from the observations themselves.

Repsold employ for the micrometers of their reading microscopes the form of construction shown in fig. 9, omitting, of course, the motion of the whole micrometer box given by the screw $s$ for those equipments in which the axis of the micrometer is supposed to remain constant in position. For example, in the reading microscopes of transit circles (see Transit Circle).

But when the relative positions of two adjacent objects or scale-divisions have to be determined (as, for example, in the case of heliometer scales), the time and space taken up by the motion of the micrometer box. One double web, fixed in the box, is pointed symmetrically, as in fig. 15, on one of the scales, by moving the whole micrometer box by means of the screw $s$; the pair of webs, moved by the screw $S$, is then pointed upon an adjacent division on the other scale. If the reading for coincidence of the movable with the fixed webs is known, we then obtain from the single reading of $S$ the difference from coincidence of the divisions of the two scales.
MICROMETER

It is generally possible so to arrange the method of observation as to eliminate the effect of an error in "the reading for coincidence of the webs" from the results. This excellent time-saving contrivance has also been used in Gill's apparatus for measuring astronomical plates (below).

Ghost Micrometer.—C. E. Burton and Sir Howard Grubb (Monthly Notices, xli. 59), after calling attention to J. von Lamont's paper (Jahrbuch der K. S. b. München, p. 187) and K. von Littrow's paper (Phil. Trans. of the Royal Acad., of Science, p. 25), and the production of the star image by means of a spider-line micrometer, have employed a similar arrangement. The system consists in ruling the micrometer-plate with a series of fine lines, and in having a pair of eyepieces or filar micrometers, set apart, with a distance which is a multiple of the length of the working line. The error of the micrometer is thus eliminated and the result is obtained in the instrument, and the slightest movement of the micrometer-plate during the division of the web, with the sensitive film in contact with the réseau-film, not only because dust particles and contact would injure the silver film, but also because the plate-glass used for the photographic plate is a perfect plane. The discrepancies produced in this way are, however, very small, and can be taken to zero by the micrometer-plate and to select a reasonably good piece of glass for the réseau.

At Greenwich, Oxford and several other observatories, instead of measuring the distances of the star's image from the opposite sides of the 6 mm. réseau-square by means of a spider-line micrometer, a glass scale, on the plan shown in fig. 16, is employed in the common focus of the objective and the eyepiece. The image of the star is set upon the intersections of the lines of the central cross, and the positions of the réseau-lines are read off by estimation to 2" of a division on the glass scale. As each division corresponds to 3 sec.

The Astrographic Micrometer or Measuring Machine.—The application of photography to exact astronomy has created the necessity for new forms of apparatus to measure the relative positions of stellar and planetary images on photographic plates, and the relative positions of lines in photographic spectra.

Especially important has been the problem of measuring the "catalogue plates" of the international Carte du ciel—a work that implies the determination of the positions of some millions of stars, that is to say, of all the stars in the 11th or 12th magnitude. The problem has been how to accomplish this work with the minimum of labour consistent with the desired accuracy. The adoption of a réseau photographic to the plate has greatly facilitated the procedure. A plate of parallel-surfaced glass has a film of silver deposited upon it. On this film is ruled a system of lines, mm. apart, and another similar system of lines parallel to this one, being displaced from it at right angles to the first, thus dividing the silvered surface of the plate into squares of 6 mm. on the side. The cutter employed to rule these lines removes the silver in fine lines from the surface of the glass. Thus, if a photographic plate, before it is exposed in the telescope, is placed with its sensitive surface nearly in contact with the silvered surface of this réseau, and if parallel lines of the second system of the plate, are allowed to fall on the silvered film through the glass, on which the film has been deposited, that light will pass through the fine lines in the silver film where the silver has been removed by the cutter, but will otherwise be intercepted by the silver film in a direction strictly parallel with the sensitive lines of the réseau. If the errors of the rectangular co-ordinates of these lines are known, the determination of the co-ordinates of any star-image on the plate becomes reduced to the comparatively simple process of measuring dimensions along the sensitive lines. The reduction of the errors for the right angles is of the order of the 5 mm. square within which that image is included. This interpolation can, of course, be accomplished with the aid of a micrometer-microscope whose optical axis is normal to the plane, provided its graduated scale is mounted on slides enabling the observer to bring the réseau-squares successively, under the microscope.

This system has an additional advantage beyond its convenience, viz., that by a slight movement of the micrometer and the sensitive film, the same distortion will be communicated both to the star-images and to the réseau-lines, and consequently its effect will be eliminated from the resulting star-co-ordinates, except in so far as the distortion within the limits of the irregular refraction in the glass is of the order of 1". An error of this order is hardly worth consideration. An originally unanticipated difficulty has arisen from the fact that the réseau-lines have not been ruled on plates of optical glass with optical surfaces, and that, in consequence of irregular refraction in the glass plate, the rays do not always pass through the central portion of the silvered film, nor is the réseau normal to the silvered surface; therefore, if the sensitive surface of the photographic plate is not in contact with the silver film of the réseau, the undeveloped photographic copy of the réseau may in such a case not be an exact reproduction of the silvered réseau. It is practically impossible to work with the sensitive film in contact of arc, the nearest estimate corresponds with a nominal accuracy of = 0.3°. This involves a loss of accuracy because, with a spider-line micrometer, the accidental error of pointing is of the order of = 0.1° of arc.

In the measuring machines in general use the field of view, as in the case of the glass-scale micrometer, is sufficiently large to include the image of the 5 mm. square. The microscope or viewing telescope is fitted with a spider-line micrometer having two screws at right angles to each other, by means of which readings can be made first for the right angles, and then the star, and finally the opposite réseau-line in both co-ordinates. This form of micrometer is of course capable of giving results of high precision, but the drawback is that the process involves a minimum of six pointings and the entering of six screw-head readings in order to measure the two co-ordinates of the star.

Gill's Measuring Machine.—Sir David Gill (Monthly Notices, R.A.S. lix. 61) devised a measuring machine which combines the rapidity of the glass-scale micro-meter with the accuracy of the spider-line micrometer, and simultaneously measures the right angles at the same time. The essential conditions of the instrument are:

1. The object glass of the micrometer-microscope is placed midway between the plate of the photographic plate and the plane of the micrometer webs.
2. The micrometer is provided with a "fixed square" 5 mm. X 5 mm., the sides of this square being parallel spider webs 4" of arc apart; the size of the square is reckoned from centre to centre of these double webs.

Greenevich Astrophotic Catalogue, vol. i., by permission of the Controller of H.M. Stationery Office. Fig. 16.—Diagram of the diaphragm in eyepieces of the micrometer used for measuring the plates of the Astronomic Catalogue.
The apparatus has been used with complete success at the Royal Observatory, Cape of Good Hope, and at Melbourne, Sydney and Córdoba.

Effects of Wear on the Micrometer Screws.—The accuracy of this apparatus has been frequently criticized on the ground that errors are produced in the screws by the effect of wear. One reply to this is that it is not difficult to determine from time to time the errors of the screws and to apply the necessary corrections to the observations. But a little consideration will show that when the plate is reversed 180° the effects of errors of the screws produced by wear are practically eliminated.

In discussing the effect of wear upon a screw, it will be convenient to imagine the thread unrolled and forming a wedge, of which we can represent the unworn bearing-side by a straight line AB (fig. 18),

![Fig. 17](image)

webs serve not only for pointing on stars to determine their co-ordinates (in manner afterwards described), but also for estimating the diameters of the star-images in terms of these 4° intervals.

3. The two micrometer screws (X and Y, fig. 17), which actuate the movable slides, have heads divided into 100 parts, one revolution = 0.5 mm.; so that ten revolutions are = 5 mm., or = the interval between two adjacent réseau-lines, or = the interval between the sides of the “fixed square.”

4. Two other screws, o, p, the heads of which are not graduated, give motions to the whole micrometer box through = 1 mm. in directions parallel to the axes of the two micrometer screws.

5. Each of the two micrometer screws X and Y move a system of six parallel webs, placed 4° apart from each other. These webs are strictly parallel, and exactly alike in pitch.

6. All the essential parts of the micrometer, including the slides, micrometer box, tube, &c., are of steel or cast-iron, so that changes of temperature do not affect the adjustments.

The necessary adjustments are the following:

1. The webs of each set of movable webs shall, inter se, be strictly parallel, and the two sets shall be strictly at right angles to each other.

2. The double webs composing the sides of the fixed square shall be strictly parallel, and shall form a true square of exactly ten revolutions of the screw on the side. 

3. The two micrometer screws shall be without sensible periodic or other errors, and exactly alike in pitch.

4. The micrometer readings for coincidence of the movable webs with the webs of the fixed square shall be exactly 0-000R and 10-000R.

5. The image of a normal réseau-square, as viewed in the microscope, shall exactly coincide with the square formed by the fixed webs—that is to say, the image of the sides of a normal réseau-square shall measure exactly 10 screw-revolutions.

Assuming that these conditions can be rigidly realized, we have the following very simple mode of operation:

1. By means of the quick rack motions A and B move the plate so as to bring the réseau-square into the centre of the field of the micrometer; then, by means of the screw heads o, p, perfect the coincidence of the “fixed square” of webs, with the image of the réseau-square.

2. By means of one of the micrometer screws X place the star’s image in the middle of the six parallel webs which are moved by X.

3. Similarly, place the star’s image in the middle of the webs moved by Y.

4. Estimate the diameter of the star’s image in terms of the 4° intervals of the movable webs.

By employing both hands, operation (1) can be made as quickly as a single pointing with the ordinary spider-line micrometer, and operations (2) and (3) can be similarly performed in the time required for a single pointing. The reading (2) is then the required co-ordinate in x and that of (3) is the required co-ordinate in y; or, if the plate is reversed, 180°, these readings have to be subtracted from 10-000R.

A general idea of the construction of the machine can be gathered from fig. 17 above, but the reader will find a detailed account of it, and of the manner in which the requisite adjustments are made, in the paper already quoted.

![Fig. 18](image)

![Fig. 19](image)

identical for revolution n and for 10-n, and thus will disappear in their effect in the mean of observations made in reversed positions of the plate. At the Cape of Good Hope, after more than 200,000 pointings had been made, the screw-errors were reetermined; the results proved the truth of the above conclusions, viz., the absolute freedom of the derived co-ordinates from the effects of wear of the screws in the mean of measures made in reversed positions of the plate.

Hinks’s Measuring Machine.—A very refined modification of the Cape machine is described by A. Hinks (Monthly Notices, R.A.S., vol. 61, p. 444), and the instrument contains many elegant mechanical and optical details due to Horace Darwin and Messrs. Zeiss respectively.

Its fundamental principle is that, by a combination of glass scales with a micrometer screw, “the chief part of the distance to be measured is read on the scale; the fractional part is read on the screews; and the error of the space is not estimated but measured by the screw.” Hinks claims that thus never more than one- or two-tenths of a revolution of the screw need be used in making the measure, and little time is lost in running the screw backwards and forwards. All this is true, but three readings instead of one for each pointing, much more figure-work in computation (especially if corrections have to be applied to the scale readings to reduce them to exact normal screw readings), are factors which involve a far greater expenditure of time than making a few additional turns of a screw in the process of measurement.

Hinks’s further claim that, in consequence of the small motion of the screw, less error is produced in the screw by errors in its threads, is true; for, although large movements of the entire apparatus produce a large amount of wear, that wear is spread over longer parts of the screw but remains the same for any particular part of the screw; the resulting errors are exaggerated towards the extremity of the range of screw employed (see Monthly Notices, R.A.S., vol. 45, p. 83), and are therefore more likely to produce error which are not eliminated on reversal of the plate in cases where the screw range is not strictly limited, and the wear therefore not strictly symmetrical.

The excellent manner in which the scales and micrometers are mounted, the employment of a compound microscope for viewing the scales, with its ingeniously arranged and admirably efficient mechanism, and the perfection of its slow movements for focusing and reading, combine to render this a most accurate and convenient instrument for very refined measures, although too slow for work in which the measures must depend on single pointings in each of two reversed positions of the plate, and where speed of working is essential.

Apparatus for Measuring Star-Spectra, &c.—These machines may be divided into three classes, viz, A, in which the motion of the slide which carries the photographic plate is measured entirely by a screw; B, in which that motion is measured by combination of a scale and screw; and C, in which the
photographic plate is fixed and the measuring microscope is moved.

The chief drawback to type A is that the errors of the screw are liable to change by wear, otherwise the apparatus, as made and used at Potsdam, is, on the whole, a convenient and accurate one. In determining the errors of the screw of the Potsdam-form of machine it is necessary to have regard to the fact that the screw is placed at one side of the slide, as in fig. 20.

The result is that, if the screw is bent—if, for example, the end of the frame next the screw-head is raised and that next the end of the bed is lowered in the diagram—a twist will be given to the web-frame, and the centre of the web will be moved nearer to the micrometer-drum than it should be, whilst the reverse effect will follow when the head has been turned 180°. This would, of course, create a perpetually varying error which would be much greater for a point particular in the middle of the web, but which would be smaller for a point near the axis of the screw and greater for a point farther from that axis. In the Potsdam form of this apparatus the measuring microscope is, for convenience, turned with the axis at right angles to the axis of the screw, and it has been found at the Cape Observatory that the periodic errors in this apparatus do vary very sensibly according as the microscope is directed to a point more or less distant from the measuring screw. Since the discovery of this fact all measurements have been made in that fixed position of the microscope with respect to the axis of the screw for which the errors of the screw have been determined.

In the apparatus of type B as made by Zeiss there are two microscopes attached to a base-plate, one of which views the spectrum-plate (or other object) to be measured, while the other views a scale that moves with the slide on which the spectrum-plate is mounted. In this way the scale can be viewed by a microscope of much higher magnifying power than can be employed for the photographed spectrum. Indeed, if the scale were subdivided to 1/50 mm. the power employed might only be limited by the sharpness of the division-lines. But for refined work this would imply the investigation of too many divisions of the scale; it is therefore more usual to divide the scale into single millimetres or half-millimetres and to provide a micrometer which subdivides the millimetre, on or by estimation into 10,000 parts. For very accurate work it is desirable that the base-plate, the slide and the scale should be of nickel steel, having the same thermal coefficient of expansion as glass.

Microscopes of type C, often seen in physical laboratories, should be at once rejected for refined measurements, because it is impossible to construct slides of such perfection that the axis of the microscope will remain absolutely normal to the surface of the plate (assumed to be a plane) throughout the range of movement. Even if a slide is made of glass, the microscope will imperfectly, the irregularity in the thickness of the lubricating oil between the bearing surfaces of the slide is apt to produce a variable error.

Bakhuizen (Bulletin de Com. perm. congr. ong. i. 164) describes a measuring-machine by Repsold, in which the micrometer-microscope tilts in the bearings of the chariot on which it moves, so that it can view either a graduated scale or the photographic plate to have, in fact, in this instrument a combination of types B and C. Experiment shows that the appearance which the micrometer-microscope will give is such as to make it impossible to determine the positions of the points on the scale in millimetres or smaller units with any degree of accuracy. Repsold in a letter to the editor of the Astrophysical Journal, xxiv. 282-302, in the modern form of his apparatus for measuring line displacements, states that he has photographed lines of stellar spectra separated by a distance of 50 μm. He states that the stellar spectra are accurately known. But in the

**FIG. 20.**

 observer imparts motion to the slide on which the travelling web is mounted, is provided with two disks at its extremities, so that the observer can use the thumb and finger of both hands in rotating it, there is no difficulty, after a little practice, in keeping the web in the axis of the instrument, and little practice the mean of the absolute errors in following the star becomes nearly zero.

In the *Astronom. Nach.* No. 3377, Repsold gives a detailed description of two forms of travel for the portable clockwork in terms of observing in this manner, to which he gives the name of the "imperial micrometer." This method of observation was very successfully employed, under Seeliger at Munich, in an extensive series of meridian observations, and, under the auspices of the Geodetic Institute at Potsdam, in telegraphic longitude operations. Still more recently the method has been largely employed at the Cape of Good Hope and elsewhere.

In the date March 1901 Dr H. Struve published an account of the application of clockwork as an aid in Repsold's method; and, later, Dr H. Cohn published a more elaborate paper on the same subject in the *Astronom. Nach.*, 3377. The method consisted in having motion transmitted to the micrometer-screw from an axis on which is mounted a disk that presses with friction-contact upon a cone that revolves uniformly by clockwork. The velocity of rotation of the micrometer-screw could therefore be varied for stars of different declination by varying the distance from the apex at which the revolving disk presses upon the revolving cone. In the Konigberg clockwork instrument used by Struve and Cohn, the clockwork was attached to the eye-end of the instrument—a mechanism that accurately provides for the periodic movement of the instrument for the application of the cone itself. In more recent continental instruments, however, the clockwork is attached to the cone, and from this cone the movement is transmitted to the rotating disk by a friction-wheel. This disk turns a worm-screw which acts on a worm-fitted wheel, that is, if the star's image is kept in bisection by the wire, both star and wire will appear at rest in the field of view.

The difference between the old and new method of observation may thus, in one sense, be described as the difference between shooting at a moving object and in shooting at one at rest. In the case of the original Repsold plan without clockwork the description is not quite exact, because both the process of following the object and correcting the aim are simultaneously performed; whilst, if the clockwork runs uniformly and the friction-disk is set to the proper distance from the cone of the star, the star will appear stationary and the instrument must be moved differentially by differential gear—a condition which is exactly analogous to that of training a modern gun-sight upon a fixed object. It is impossible in this article to give a detailed description of the instrument. But the reader is referred to *Astronom. Nach.*, 3377, for an illustrated account of the original Repsold's instrument and to the History and Description of the Cape Observatory for a complete description of the modern form of its application to the Cape transit circle, with and without clockwork.

**The Hartmann Spectrocomparator.** For accurate measurement of the displacements of lines of stellar spectra which are produced by the relative motion of star and observer in the line of sight, a very beautiful instrument has been devised by Dr. J. Hartmann of Potsdam, as described by him in the *Abhandlungen der Astrophysikalischen Forschungs- u. p. Kiel, B. 18, 21, 3 (1906). An English translation of this paper is given in the *Astrophysical Journal,* xxiv. 282-302. The method originally used by Huggins, who first conceived and proved the possibility of measuring stellar velocities in the line of sight, was to measure with a far micrometer the displacement of some well-known line in a stellar spectrum relative to the corresponding line of a terrestrial spectrum. Vogel of Potsdam introduced the method of photographing stellar and terrestrial spectra on the same plate, in order to obtain a direct and obvious advantage in the ease and precision of observation. Vogel and his associates employed one or other form of measuring machine, provided with a microscope having single or double parallel webs which could be successively pointed on the photographed lines of the star spectrum and the lines of the terrestrial spectrum. To derive the stellar velocity in the line of sight relative to the observer it was then necessary to assume that the normal wave-lengths of the stellar and terrestrial spectra are accurately known. But in the
complex spectra of stars of the solar type this is by no means the case; for, as Dr. Hartmann remarks, "in the first place the lines in these spectra are so numerous that their complete measurement and reduction would require many days, and in the second place a rigorous reduction of such material has hitherto not been at all possible because the wave-lengths of the lines are not known with sufficient accuracy. On this account, observers have until now limited themselves to a partial treatment of such spectra, measuring only a small number of lines, whereby the major part of the rich material present in the plate remains unutilized." But the spectroscopes that can be employed for stellar spectrographs are not sufficiently powerful to separate fully lines which are very closely adjacent, and therefore a line, assumed to be of a known wave-length, may be apparently displaced by the near neighbourhood of an unknown line. Hartmann overcame these and many other difficulties by directly superposing the image of the spectrogram of a star, having iron comparison lines, upon the image of a spectrogram of the sun taken also with iron comparison lines.

The apparatus for this purpose is shown in fig. 21, its principle of construction is shown in figs. 22 and 23. The solar spectrograph is attached by clamps to the plate $A_1$, the stellar spectrograph to the plate $A_2$. The plate $A_1$ is mounted on the dove-tailed slide $B_1$, upon the metallic stage $T$, and can be moved to right or left relative to $T$ by the micrometer-screw $S$; whilst the plate $A_2$ is mounted on the dove-tailed slide $B_2$ and can be moved at right angles to its greatest length by the screw $G$. The micrometer-screw $S$ has a pitch of 0.5 mm., its head is divided into 100 parts. Two spiral springs underneath press the plate $B_1$ with its agate end-bearing against the rounded end of the screw $S$. The whole number of revolutions of the screw is read by the scale $X$ (fig. 23). The whole stage $T$, carrying both spectrographs, can be moved from right to left on the steel cylinder $Z$, by turning the head $K$, on the axis of which is a pinion that gears into a toothed rack attached to the lower side of the cylinder $Z$. A scale $N$ on the cylinder $Z$ serves for setting the slide to any required position. The preliminary conditions of measurement are:

1. The centre of both spectrographs shall be parallel to the axis of the cylinder $Z$.
2. The distance between the centres of the two spectrographs shall be equal to the distance between the optical axes of the two viewing microscopes.
3. The scales of the images formed in the focus of the eyepiece common to both microscopes shall be identical.

To fulfill condition (1) the plates $A_1$ and $A_2$ are mounted in circular slides, whose centres are $E_1$ and $E_2$ respectively, so that by means of the screws $D_1$, $D_2$ with their corresponding opposing springs $P_1$ and $P_2$ the operation can be very easily accomplished. To fulfill condition (2) the two microscopes whose object glasses are $O_1$ and $O_2$ (fig. 22) are attached to the plate $L$, their optical axes being normal to the stage $T$. The screw $Q$ serves to adjust the axis of $O_2$ to coincidence with the centre of the lines of the solar spectrograph, and the screw $G$ then serves to move the slide $B_2$ till the optical axis of $O_2$ is coincident with the centre of the lines of the stellar spectrograph. Suppose now the solar spectrogram to be viewed in the focus of $O_1$, and the converging rays to be reflected by the prisms $P_1$ and $P_2$, till an image is formed in the focus of the eyepiece at the point where the axis of the eyepiece intersects
the upper face of the prism $P_4$. Then if the prism $P_4$ is cemented to $P_3$, a sharp image of such lines of the solar-spectrograph as are visible in the field of view will be seen in the eyepiece. If the stellar spectrograph is viewed in the focus of $O_4$ and the converging rays are reflected by the prism $P_3$ to $P_4$, no image would be seen in the eyepiece, for the rays would pass out directly through the parallel glass plate which is formed by the cementing together of the prisms $P_3$ and $P_4$. But if the cemented face of $P_4$ is silvered, then the lines of the stellar spectrogram would be seen in focus of the eyepiece and the image of the solar spectrograph would be obliterated. Therefore, if one-half of the cemented face of $P_4$ is silvered, it becomes possible to view, side by side, one-half of the image of the solar spectrograph formed by $O_4$ and one-half of the image of the stellar spectrograph formed by $O_3$. A prism half silvered in this way is provided, which enables the observer to compare the equality of scale of both photographs. If, for example, it is found that the image of the solar spectrograph is the larger of the two, it becomes necessary to adjust the object glass $O_4$ farther from the stellar spectrograph. This has the effect of forming the image of the latter farther from the observer's eye, and so it becomes necessary to turn the handle of the rack-pinion $V$ in such a way as to move the prisms $P_3$ and $P_4$ nearer to $P_2$ till the lines of the stellar spectrograph are again sharply in focus. The effect of turning the pinion $V$ is, of course, to displace the focus both of the solar and stellar spectrographs in the field of the eyepiece, but this displacement is easily restored by the focussing screws $O_1$ and $O_2$. By successive adjustments of this kind condition (3) can be accurately realized.

These three adjustments having been made, the prisms $P_3$ and $P_4$ are removed and replaced by another prism in which the silvering is arranged as in fig. 24, where the hatched lines denote the silvered surfaces. The narrow tongues of the silvered surface will now reflect corresponding parts of the star-spectrograph, and will obliterate corresponding parts of the solar spectrograph—as shown in figs. 25 and 26. Fig. 25 shows the stellar and solar lines of the two spectrographs in coincidences, whilst the metallic lines of comparison are non-coincident. Fig. 26 shows the metallic lines of comparison in coincidence whilst the solar and stellar lines are non-coincident. It is obvious that these two conditions can be produced at the will of the observer by simply turning the screw $S$, and that the difference of the readings of the screw-head, which are required to reproduce the two conditions in question, gives a measure of the displacement of the stellar lines relative to the solar lines. If then the screw-value in kilometres per second is known for the neighbourhood of each of the comparison lines employed, the radial velocity of the star can be independently derived directly from coincidences made in above manner in the neighbourhood of each comparison line. For the special purpose of determining the solar parallax this instrument has been used in a most refined and perfect manner by Dr Halm at the Cape of Good Hope (Annals of the Cape Observatory, vol. x. part 3).

**MICRONESIA**

One of the three great divisions of the oceanic islands in the central and western Pacific. Lying to the north of Melanesia, it embraces the following groups: Mariana, Pelew, Caroline, Marshall and Gilbert. See articles under these headings, and Pacific Ocean (section on Islands).

The Micronesian islands form in the main a branch of the Polynesian race, but distinguished from it by well-marked differences in appearance, language and institutions. Many of the islanders, however, show signs of hybridism. The proximity of Japan and the Philippines on the west, and of the Papuan

1 There are authenticated instances of Japanese junks, with living people in them, having been found in various parts of the North Pacific. In 1814 the British brig "Forester" met with one off the coast of California (about 30° N. lat.), with three living men and fourteen dead bodies on board. In December 1832 a Japanese junk arrived at the Hawaiian Islands with four of the crew living. If these junks could cross the Pacific in the latitude of Hawaii it is not at all unlikely that others running in a south-easterly direction would reach some of the many atolls which stretch over about 35° of longitude, forming the Caroline and Marshall archipelagoes.

The traditions of the Gilbert Islanders tell us that their islands
and South Polynesian islands on the south and south-east, suggests, what in fact is found, a combination of races. In some places the oblique Mongolian eye is noticed, and (together with certain Indo-Chinese customs) there is often a scantiness of beard and general "Malay" look, which increases westwards, and seems to imply relations with the archipelago subsequent to the departure thence of the pure Polynesians. In the Gilberts the traces of Polynesian (Samoan) influences are evident, and are confirmed by tradition. Among the Carolines and the Marshalls darker and more savage communities are found, suggesting a Melanesian element, which is further traceable in the Ebon (Marshall) and other languages.

Each of the four main groups, viz. the Caroline, Marshall, Gilbert and Ladrone (Mariana), from long isolation, has developed ethnological peculiarities of its own. The most advanced folk were the "Chamorros" of the Ladrones, owing to the greater natural resources of the islands, and perhaps more frequent contact with influences from the west; but as a separate people they no longer exist, having been nearly exterminated by the Spaniards in the 17th century. Next in advancement come the Caroline islanders. The general Micronesian type is a well-proportioned rather slightly built figure, with small and regular features; head high and well proportioned, but forehead rather retreating and narrow at the temples; cheek bones and chin slightly prominent; straight black hair, lanker than that of the Polynesians, color somewhat darker than the Polynesians, the Marshalls being darker and more vigorous than the Carolines, while the Gilbert type, though smaller than the latter, is still darker and coarser. The upper class greatly surpasses the common people in physique and intelligence.

There is a division of society into septs or clans, the membership of which constitutes the closest tie. Persons of the same sept must not intermarry, and when two islands or communities meet in war the members of one sept, however widely separated by distance of space or time, will not injure or fight with each other. Each community is usually composed (but there are local differences) of (1) the upper class of paramount leaders; (2) the common people of the island (tamol or iros); (2) a lower but still noble class; and (3) common people, mostly without rights of property. These last are only allowed one wife. Here and there are traces, as in Tonga, of a spiritual sovereign, the descendants probably of a conquered dynasty. Succession is through the female side, which assures to women a certain position, and leads besides to some curious results (see paper by J. S. Kuykendall in *Das Ausland*, 1890, No. 27). The upper class consists of the chieftains and chiefs, and the leaders of expeditions; tattooing is generally done by them, the amount increasing with a man's rank; the custom here still has definite religious associations. Both sexes are tattooed.

The Carolines are the boldest and most skilful navigators in the Pacific. Their voyages of many months' duration, in great canoes sailing with outrigger to windward, well-provisioned, and depending on the skies for fresh water, help to show how the Pacific people, from the earliest time, were accustomed to living on the shell of the *Tridacna gigas* (the largest bivalve known), was formerly used in the Carolines, probably by the old builder race.

The dialects of Micronesia, though grammatically alike, differ widely in certain respects. The chief characteristics of the Polynesian, with Malay affinities, and peculiarities such as the use of infixes and inseparable pronouns and, as in Tagal, of the infix to denote changes in the verb; in the west groups there is a tendency to use the palatal sounds and also the palatal postalveolars, in the palatals *ch, j, sh*, the dental *th, ch* (the last perhaps only in foreign words), which is alien to the Polynesian. These letters are wanting in the Gilbert language, which differs considerably from all the others, which are much alike with the Polynesian. Most words take the accent on the penult. In some of the dialects there appears to be no true article, but in the Gilbert Islands the Polynesian *te* is used for both definite and indefinite article. Gender is sexual only. Number in the noun is either gathered from the people wepeled from the west and also from the east. Those who came from the east are expressly said to be from Samoa. Those from the west wepeled from the north. There are also traditions of the arrival of other strangers at some of these islands. On the island of Peru, in the Gilbert group, in 1899 there was still the remnants of a large proach which, from the description given, appears to have been those used in the Indische Archipelago.
may be so disposed that the two minerals have a definite relation between their crystallographic axes (parallel growth). The quartz, which generally occurs as angular patches, at other times it forms club-shaped, curved or vermiciform threads (vermicular micropegmatite, myrmekite), and then some authors consider that the felspar has been corroded and the quartz fills the spaces thus produced (quartz de corrosion of French petrographers). Micropegmatite is often so fine grained that even in the thinnest sections and with high powers it cannot be resolved into its components. This fine micropegmatite resembles threads, having a divergent arrangement. In some rocks the whole ground mass consists of such spherulitic growths of fibrous micropegmatite (see quartz—porphyry); in their centres there is often a quartz or felspar crystal; the outer boundaries of the spherulites are not usually circular but irregular owing to the interlocking of adjacent spherulites at their margins ("granophyric structure"). Micrographic structures may occur in other minerals, e.g., quartz and garnet, cordierite, epidote or hornblende, augite and felspar, but are less common, and the name micropegmatite is usually reserved for aggregates of quartz and felspar.

In rocks where micropegmatite frequently occurs (e.g., granite, porphyry, quartz—porphyry, quartz—diorite) it is usually the last product of consolidation, and represents the mother liquor left over after the other minerals had separated out in more or less perfect crystals. Hence it has no definite form of its own, but fills the irregular interstices between the earlier crystals. For that reason it has been compared to an eucetic, and supposed to be the mixture of quartz and felspar which has the lowest fusion point. Eutectic is common in alloys and often have a very perfect form. The composition of the mixture of quartz and orthoclase has been estimated to contain 70-75% of the latter. This theory, however, is not without its difficulties; analyses of micropegmatite prove that its composition is by no means constant (this may perhaps be due to sand admixtures of soda and lime, felspar, etc.), and experimental researches on the fusion of mixtures of quartz and felspar have not yet shown that there is a definite mixture which melts at a lower temperature than any other. Furthermore micropegmatite is not always the last consolidation product, as an eutectic should be, but may occur as well-shaped phenocysts lying in a felsitic or glassy matrix which solidified at a still later time. Micrographic structures in the minerals of igneous rocks prove only that these minerals crystallized simultaneously.

**MICROSCOPE** (Gr. μύκρος, small, σκόπειν, to view), an optical instrument for examining small objects or details of such objects; it acts by making the angles of vision under which the images appear greater than when the objects themselves are viewed by the naked eye.

Microscopes are distinguished as simple and compound. A simple microscope consists of a single positive lens, or of a lens combination acting as a single lens, placed between the eye and the object so that it presents a virtual and enlarged image. The compound microscope generally consists of two positive lens systems, so arranged that the system nearer the object (termed the objective) projects a real enlarged image, which occupies the same place relatively to the second system (the eyepiece or ocular) as does the real object in the simple microscope. An image is therefore projected by the ocular from the real magnified image produced by the objective with increased magnification.

**History of the Simple Microscope.**—Any solid or liquid transparent medium of lenticular form, having either one convex and one flat surface or two convex surfaces whose axes are coincident, may be called a "magnifier," the essential condition being that it shall refract the rays which pass through it, and cause widely diverging rays to become either parallel or but slightly divergent. Thus if a minute object be placed on a slip of glass, and a single drop of water be placed upon it, the drop will act as a magnifier in virtue of the convexity of its upper surface; and so that when the eye is brought sufficiently near it (the glass being held horizontally) the object will be seen magnified. Again if a small hole be made in a thin plate of metal, and a single drop of water be inserted in it, this drop, having two convex surfaces, will serve as a still more powerful magnifier. There is reason to believe that the magnifying power of transparent media with convex surfaces was very early known. A convex lens of rock-crystal was found by Leopard among the ruins of the palace of Nimrud; Seneca describes hollow spheres of glass filled with water as being commonly used as magnifiers.

The perfect gem-cutting of the ancients could not have been attained without the use of magnifiers; and doubtless the artificers who executed these wonderful works also made them.

Convex glass lenses were first generally used to assist ordinary vision as "spectacles"; and not only were spectacle-makers the first to produce glass magnifiers (or simple microscopes), but by them also the telescope and the compound microscope were first invented. During the Thirty Years' War the simple microscope was widely known. Descartes (Dioptrique, 1637) describes microscopes wherein a concave mirror, with its concavity towards the object, is used, in conjunction with a lens, for illuminating the object, which is mounted on a point fixing it at the focus of the mirror. Anthony van Leeuwenhoek appears to be the first to succeed in grinding and polishing lenses of such short focus and perfect figure as to render the simple microscope a better instrument for most purposes than any compound microscope then constructed. At that time the "compass" microscope was in use. One leg of a compass carried the object, and the other the lens, the distance between the two forming an angle, which was adjustable in use and permitted the manipulation of the object by hand. Robert Hooke shaped the minutest of the lenses with which he made many of the discoveries recorded in his Micrographia from small glass globules made by fusing the ends of threads of spun glass; and the same method was employed by the Italian Father Di Torre. Early opticains and microscopists gave their chief attention to the improvement of the simple microscope, the principle of which we now explain.

**Simple Microscope**

**Position and Size of the Image.**—A person with normal vision can see objects distinctly at a distance varying from ten inches to a very great distance. Objects at different distances, however, are not seen distinctly simultaneously, but in succession. This is because the retinal image has afo, and the more distinctly are the details of the eye which can be seen, the shorter is the length of the eye, the greater is the distance, this being proportional to the inclination of the eye which so alter the focal length of its crystalline lens that images of objects at different distances can be produced rapidly and distinctly one after another upon the retina.

The angle under which the object appears depends upon the distance and size of the object; or, in other words, the size of the image on the retina is determined by the distance and the dimensions of the object. The ratio between the real size of the object $y$ (fig. 1) and the distance $l$, which is equal to the tangent of the visual angle $w$, is termed the "apparent size" of the object. From the figure, which represents vision with a motionless eye, it is seen that the apparent size increases as the object under observation is approached. Thus the greater the visual angle $w$, the more distinctly are the details of the object perceived. On the other hand, as the observer recedes from the object, the apparent size, and also the image on the retina diminishes; details become more and more confused, and gradually, after a certain distance, disappear altogether, and ultimately the whole configuration of the object as a whole is no longer recognizable. This case arises when the visual angle, under which the object appears, is approximately a minute of arc; it is due to the physiological construction of the retina, for the ends of nerve fibres, which receive the impression of light, have themselves a definite size. The lower limit of the resolving power of the eye is reached when the distance is approximately 3438 times the size of the object.

If the object be represented by two separate points, these points would appear distinct to the normal eye only so long as the distance between them is at the most only 3438 times smaller than their distance from the eye. When the latter distance is increased still further, the two appear as one. Therefore when it is desired to distinctly recognize exceedingly small objects or details of such, they are brought as near as possible to the eye. The eye is strained in bringing its focal length to the smallest possible amount, and when this strain is long continued it may cause pain. When the shortest distance obtained by the highest strain of accommodation is insufficient to recognize small objects, distinct vision is possible at even a shorter distance by placing a very small diaphragm
between the eye and the object, the pencils of rays proceeding from the object-points, which otherwise are limited by the pupils of the eye, being thus restricted by the diaphragm. The object is then projected with such acute pencils on the plane focused for, in this case on the plane on which the eye can just accommodate itself, that the circle of confusion arising there is still so small that it is below the limit of angular distinctness and on that account appears as a sharp point. However, the loss of light in this process is extraordinarily large, so that only most intensively illuminated objects can be investigated.

A naked short-sighted eye, which would be corrected for distant objects by a spectacle glass of −10 diopters, may approach the object in such a way as to see the object clearly and has no need of any correction without any strain whatever. For the observation of small objects, a myopic eye is consequently superior to a normal eye; and the normal eye in this turn is superior to the hypermetropic one. When the object is within the range of myopia, which is considered by some as being magnifying glass or the simple microscope is necessary. As a rule the magnification is not demanded from the former, but a larger field of view, whilst the simple microscope should ensure powerful magnification in the smaller fields. The magnifying power of the eye is naturally limited, but is enlarged by the use of different lenses. The magnification resulting from the formation of rays in a microscope is given by

\[ \tan \frac{w'}{w} = \tan \frac{1}{f'} = V, \]

(1)

in which \( f' = H' F' \) is the image-side focal length (see LENS). Since the lens is bounded by air, the image- and object-side focal lengths \( f \) and \( f' \) are equal. The value \( 1/f \) or \( V \) in (1), is termed the power of the lens. In most cases the number of \( " \) diameters, of the simple microscope is required, i.e., the ratio between the apparent sizes of the object when observed through the microscope and when viewed by the naked eye. When a person of normal vision views a small object, he brings it to the distance of distinct vision, which would average about 10 in the apparent size is then (fig. 1) \( \tan w = y/w, \) where \( l = 10 \) in., whilst the apparent size of the object viewed through the magnifying glass would result from the formula (1) \( \tan w = y/f. \) Consequently the number of diameters

\[ N = \tan w/\tan w = y/f, l/y = l/f = V, l; \]

(2)

it is thus equal to the magnifying power multiplied by the distance of distinct vision, or the number of times that the focal length is contained in \( l. \)

Since this value for the distance of distinct vision is only conventional, it is understood that the capacity of the simple microscope given in (2) holds good only for eyes accustomed to examine small objects 10 in. away; and observation through the microscope must be undertaken by the normal eye with passive accommodation. A lens of 1 in. focal length must be spoken of, according to this notation, as a \( \times 10 \) lens, a lens of \( 1/2 \) in. focal length as a \( \times 20 \) lens, etc. One of the main considerations in the design of a normal eye free from accommodation is immaterial for determining the magnification. A \( \times 10 \) magnification is, however, by no means guaranteed to a myopic eye of −10 D by a lens of 1 in. focus. Since this short-sighted individual can only see clearly objects at a distance of 10 in., he must accommodate himself to 4 in. distance, it follows (to him) the apparent size is \( \tan w = y/4; \) and to secure convenient vision through the lens the short-sighted person would bring the object to a distance of 5 in. from the eye. The magnification, resulting from the simple microscope of 1 in. focus, is here \( N = \tan w/\tan w = y/f, f/y = f/4 = 4. \) Thus, while a lens of 1 in. focal length assures to the normal-sighted person a \( \times 10 \) magnification, it affords to the short-sighted individual only a \( \times 5 \) magnification, which is of less use to him than the hypermetropic one to the observer of normal sight. From this it appears that each observer obtains specific advantages from one and the same simple microscope, and also that each individual observer can obtain different magnifications by either using different accommodations, or by viewing in passive accommodation.

Regulation of the Rays.—In using optical instruments the eye in general is moved just as in free vision; that is to say, the attention is fixed upon the individual parts of the image one after another, the eye being turned in its cavity. In this case the eye is always directly placed on the same part of the image which is wished to be viewed exactly falls upon the most sensitive portion of the retina, viz., the macula lutea (yellow spot). Corresponding to the size of the yellow spot only a small fraction of the image appears particularly distinct, and the rest are reproduced on the retina on the regions surrounding the yellow spot will also be perceived, but with reduced definition. These external and less sensitive parts of the retina, therefore, merely give information as to the general character of the objects and to a certain extent act as a guide-post in order to show quickly and conveniently, although not distinctly, the places in the image which should claim special attention. Vision with a motionless eye, or "direct vision," is obtained when the rays are focused in the eye on a small central portion of the retina. Vision with a movable eye, or "indirect vision," gives exact information as to the parts of the object one after another.

The simple microscope permits such vision. If the instrument has a sensible lens diameter, and is arranged so that the centre of rotation of the eye can coincide with the intersection of the principal rays, the lens can then form with the eye a centred system. Such lenses are termed "lenses for direct vision." By moving the eye about its centre of rotation M the whole field can be examined.

The magnification of the magnified image is that of the field of view. The selection of the rays emerging from the lens and employed for forming the image is undertaken by the pupil of the eye which, in this case, is consequently the exit pupil of the instrument. In fig. 3 of P'Pi', P', is the image of the objective P'Pi', which is formed by the lens, limits the aperture of the pencils of rays on the object-side; consequently it is the entrance pupil of the instrument. Since the exit pupil moves in observing the whole field, the entrance pupil also moves. The principal rays, which on the object-side connect the object-points with the centre of the entrance pupil, intersect the axis on the image-side at the centre of rotation M of the eye. M is therefore the intersection of the principal rays.

So long as the exit pupil is completely filled the brightness of the image will be approximately equal to that of free vision. If, however, we fix the points lying towards the margin of the field of view, the diaphragm gradually cuts off more and more of the rays which are necessary to fill the pupil, and in consequence the brightness gradually falls off to zero. This vignetting can be observed in all lenses.

In most cases, and also in corrected systems, the intersection of the principal rays is no longer available for the centre of rotation of the eye, and this kind of observation is impossible. In some instruments observation of the whole available field is only possible when the head and eye are moved at the same time. In the diagram shown in fig. 4 shows the position of the diaphragms to be considered in this kind of observation. P'P, is the image of the pupil, P, the exit pupil, and GG the diaphragm. The intersection of the principal rays in this case is virtual, and the pupil is placed in the middle of the entrance pupil or of the exit pupil. By head and eye motion the various parts of the whole field can be viewed one after another. The distance of the eye from the lens is here immaterial. In this case also the illumination must fall to zero by the vignetting of the pencils coming from objects at the margin of the field of view. C, G, D, and A are the outermost rays which can pass through the instrument.

Magnifying glasses are often used for viewing three-dimensional objects. Only points lying on the plane focused for can be sharply reproduced in the retina, which acts as object-plane to the retina.
components required weaker curvatures and permitted of being more correctly manufactured, and, more particularly, the advantage of reduced aberrations was the predominant factor.

Doublets (fig. 10) is a combination of two plano-convex lenses, the focal lengths of which are in the ratio of 3:1: the plane Wollaston, Fraunhofer, Wilson, Steinheil, Chevalier (Brücke).

**Fig. 8.** **Fig. 9.** **Fig. 10.** **Fig. 11.** **Fig. 12.**

sides are turned towards the object, and the smaller of the two lenses is nearer the object. This construction was further improved (1) by introducing a diaphragm between the two lenses; (2) by altering the distance between the two lenses; and (3) by splitting the lower lens into two lenses. Triplets are employed when the focal length of the simple microscope was less than χ-produced. When using such constructions the image results from spherical aberration, and the chromatic errors are very small. Similar doublets composed of two plano-convex lenses are the Fraunhofer (fig. 9) and the Wilson (fig. 10). Axial aberration is reduced by distributing the refraction between two lenses and by placing the two lenses farther apart the errors of the pencils of rays proceeding from points lying outside the axis are reduced. The Wilson has a greater distance between the lenses, and also a reduction of the chromatic difference of magnification, but compared with the Fraunhofer it is at a disadvantage with regard to the size of the free working distance, i.e., the distance of the object from the lens surface nearer it.

By introducing a dispersive lens of flint the magnifying glass could be corrected for both chromatic and spherical aberrations. Brownie's "plaque ray" lens and the Steinheil "aplanatic" lens (fig. 11) are of this type. Both yield a field of good definition free from colour.

The manner in which the eye uses such a lens was first effectively taken into account by M. von Rohr. These anastigmatic lenses, which are manufactured up to X 40, are chromatically and spherically corrected, and for a middle diaphragm the errors of lateral pencils, distortion, astigmatism and coma are eliminated. Peepholes for such a diaphragm is rendered possible by showing the head and eye while the lens is held steady. Even in powerful magnifications a good image exists in all parts of a relatively large field, and the free working distance is fairly large.

The more highly powered these lenses were, the corrections proposed by Chevalier and carried out by E. Brücke must be noticed (fig. 12). To an achromatic collective lens, which is turned towards the object, a dispersive lens is combined (this type to a certain extent by correcting for spherical aberations). The distance of the collective and dispersive members magnification can be varied. Through the large free working distance, which for certain work offers great advantages, the size of the field of view is diminished.

Two magnifying glasses for direct vision the eye must always be considered. The lens is brought as close as possible to the eye so as to view as large a field as possible. The watchmaker's glass is one of the earliest forms of this kind. Gallant showed how to correct these lenses for oblique, the plane light, etc., to eliminate distortion and astigmatism when the centre of rotation of the eye coincided with the point where the principal rays crossed the axis. Von Rohr fulfilled this condition by constructing the Veran lens, which are lens system for such a purpose. The device is similar, but the distance of the collective and dispersive members magnification becomes varied. Through the large free working distance, which for certain work offers great advantages, the size of the field of view is diminished.

Sir David Brewster found that Wollaston's form worked best when the two lenses were hemispheres and the central space was filled up with a transparent cement having the same refractive index as the glass; he therefore used a sphere and provided it with a groove at the equator (see fig. 6). Coddington employed the same construction, and for this reason this device is called the Coddington-Wollaston. Although he brought the Wollaston-Brewster lens into general use, he was never the inventor nor claimed to be. This lens reproduced all points of a concentric spherical surface simultaneously sharp. A construction also employing one piece of glass is the Stanhope (fig. 7) which is due to Brewster. This is a glass cylinder, the two ends of which are spherical surfaces. The more strongly curved surface is placed next the eye, the other serves at the same time as specimen carrier. This lens is employed in articles found in tourist resorts as a magnifying glass for miniature photographies of the locality.

**Fig. 5.** **Fig. 6.** **Fig. 7.**

Doubllets, etc.—To remove the errors which the above lenses showed, particularly when very short focal lengths were in question, lens combinations were adopted. The individual

All points lying out of this plane are reproduced as circles of confusion. The central projection, of which the centre is the middle point of the entrance pupil on the plane focused for, will show in weaker systems, or those very much stopped down, a certain finite size of the image. As the focal length of the lens, which is out of the plane focused for, and which are projected with circles of confusion so small that they appear to the eye as sharp points, will include the sharp object relief, and determine the depth of definition of the lens. With increasing magnification the object of the lens and the plane in which it rests are brought to the observer so that the confusions are greater in consequence of the shorter focal length. Very powerful simple microscopes have hardly any depth of definition so that in fact only points lying in one plane can be seen sharply with or without confusion.

**Illumination.—** So long as the pupil of the observer alone undertakes the regulation of the rays there is no perceptible diminution of illumination in comparison with the naked eye vision. The lesser aperture, however, the case is with the microscope, which takes place in the passage of the light through the glass surfaces. In a lens with two bounding surfaces in air there is a loss of about 9%: and in a lens system consisting of two separated lenses, i.e. with four surfaces in air, about 17%. Losses due to absorption are almost zero when the lens are very thin, as with lenses of small diameter. A very marked diminution in illumination occurs, however, when the exit-pupil of the instrument is smaller than the pupil of the eye. In such instruments an arrangement is often required to immensely illuminate the object.

**Forms of the Simple Microscope.—** If the ordinary convex lens be employed as magnifying glass, great aberrations occur even in medium magnifications. These are: (1) chromatic aberration, (2) spherical aberration and (3) astigmatism (see Aberration).

When the pupil regulates the aperture of the rays producing the image the aberrations of the ordinary lenses increase considerably with the magnification, or, what amounts to the same thing, with the increase of the air in the surfaces of the glass. If the diameter of the pupil is too large, and diaphragms must be employed which strongly diminish the aperture of the pencil, and so reduce the errors, but with a falling off of illumination. To reduce the aberrations Sir David Brewster proposed to employ in place of the lens, transparent minerals of high refractive index and low dispersion. In this manner lenses of short focus can be produced having lower curvatures than glass lenses necessary. The diamond has the requisite optical properties, its index of refraction being about 1-6 times as large as that of ordinary glass. The spherical aberration of a diamond lens can be brought down to one-ninth of a glass lens of equal focus. Apart, however, from the cost of the mineral and its very difficult working, a source of error lies in its want of homogeneity, which causes a double or even a triple image. Similar attempts made by Pritchard with sapphires were more successful. With this mineral also spherical and chromatic aberration are a fraction of that of a glass lens, but, but, which involves the use of a plane image, is fatal to its use. Improvements in glass lenses, however, have rendered further experiments with precious stones unnecessary. The simplest was a sphere of glass, the equator of which (i.e. the mount) formed the diaphragm. Wollaston altered this by taking two plano-convex lenses, each of which had large curvatures, and other and employing a diaphragm between the two parts (fig. 5).

Sir David Brewster found that Wollaston's form worked best when the two lenses were hemispheres and the central space was filled up with a transparent cement having the same refractive index as the glass; he therefore used a sphere and provided it with a groove at the equator (see fig. 6). Coddington employed the same construction, and for this reason this device is called the Coddington-Wollaston. Although he brought the Wollaston-Brewster lens into general notice, he was never the inventor nor claimed to be. This lens reproduced all points of a concentric spherical surface simultaneously sharp. A construction also employing one piece of glass is the Stanhope (fig. 7) which is due to Brewster. This is a glass cylinder, the two ends of which are spherical surfaces. The more strongly curved surface is placed next the eye, the other serves at the same time as specimen carrier. This lens is employed in articles found in tourist resorts as a magnifying glass for miniature photographies of the locality.

Doubllets, etc.—To remove the errors which the above lenses showed, particularly when very short focal lengths were in question, lens combinations were adopted. The individual
the stage, a black or white plate, forming a dark or light background, can be swung underneath the specimen.

When the recognition of the arrangement in space of small objects is desired, a stereoscopic lens can be used. In most cases refracting and reflecting systems are arranged so that the natural interpupillary distance is reduced. Stereoscopic lenses can never be powerful systems, for the main idea is the recognition of the depth of objects, so that only systems having a sufficient depth of definition can be used. Stereoscopic lenses, operating to faulty construction, give a false idea of space, ignoring the errors which are due to the alteration of the interpupillary distance and the visual angles belonging to the principal rays at the object-side (see Binocular Instruments).

**Compound Microscope**

The view held by early opticians, that a compound microscope could never produce such good images as an instrument of the simple type, has proved erroneous; and the principal attention of modern opticians has been directed to the compound instrument. Although we now know how the errors of lenses may be corrected, and how the simple microscope may be improved, this instrument remains with relatively feeble magnification, and to obtain stronger magnifications the compound form is necessary.

By compound two lenses or lens systems separated by a definite interval, a system is obtained having a focal length considerably less than the sum of the focal lengths of the separate systems, and \( f' \) the focal lengths of the combination, \( f_1 \) and \( f_2 \) the focal lengths of the two components, and \( \Delta \) the distance between the inner focal points of the components, then \( f = f_1 f_2 / f_1 + f_2 - \Delta \) (as seen LENS). \( \Delta \) is also equal to \( f_1 - f_2 \). When the acceptance \( f' \) are always on the image side, while the unaccented are on the object side. From this formula it follows, for example, that one obtains a system of \( \frac{1}{2} \) in. focal length by compound two positive systems of 1 in. each, whose focal lengths, turned towards one another, are separated by \( \frac{1}{2} \) in.

A microscope objective being made in essentially the same way as a simple microscope, and the front focus of the compound being situated before the front focus of the objective, the magnification due to the simple system makes the free object distance greater than that obtained with a simple microscope of equal magnification. Moreover, this distance between the object and eye is substantially increased in the compound microscope by the stand; the inconveniently nearly always to the eye which may arise, for example by warming the object, are also avoided. The convenient and rapid change in the magnification obtained by changing the eyepiece or the objective is also a special advantage of the compound form.

In the commonest compound microscopes, which consist of two positive systems a real magnified image is produced by the objective. This permits researches which are impossible with the simple microscope. For example, the real image may be recorded on a photographic plate; it may be measured; it can be physically altered by polarization, by spectral analysis of the light employed by absorbing layers, &c. The greatest advantage of the compound microscope is that the object is magnified and the much more nearly completely than is possible in the simple form. According to the laws of optics it is only possible either to portray a small object near one of the focal points of the object with wide pencils, or to produce an image from a relatively small area of the object with narrow pencils. The simple microscope is subject to the limitation. As we shall see later, one of the principal functions of the microscope objective is the representation with wide pencils. In that case, however, in the compound microscope a small object may always be represented by means of wider pencils, one of the focal points of the object (not of the collective system) being near it. For the eyepiece the other rules hold; the object is represented by narrow pencils, and it is here that the compound microscope essentially departs from the simple form. A distinct improvement was made in its construction in the two centuries following the discovery. In 1668 the Italian Divini employed several doublets, i.e. pairs of plano-convex lenses, and his example was followed by Giordani von Ach. But even with such moderate magnification as these instruments permitted many faults were apparent. A microscope, using concave mirrors, was proposed in 1672 by Sir Isaac Newton; and he was succeeded by Barker, R. Smith, B. Martin, D. Brewster, and, above all, Amici. More recently these catastrophic microscopes were disregarded because they yielded unfavourable results. From 1830 onwards many improvements were made in the microscope objective; these may be best followed from a discussion of the faults of the image.

**Position and Size of Image.**—In most microscopic observations the object is mounted on a plane glass slide or about \( 0.06 \) in. thick, embedded in a liquid such as water, glycerine or Canada balsam, and covered with a plane cover-slip of about \( 0.008 \) to \( 0.006 \) in. thick, called the cover-slip. If we consider the production of the image of an object of this kind by the systems of a compound microscope shown in fig. 13, the objective \( L_1 \) forms a real magnified image \( O'O' \); the eyepiece \( y' \) produces a virtual image \( y'' \) of what in front of the front focal point \( F_1 \) of the objective. Let \( OQ = y, O'O'' = y'' \) the focal distance of the image \( F'O' = \Delta \), and the image-side focal length \( f' \), then the magnification

\[
M = y''/y = \Delta f'/f'.
\]

The distance \( \Delta \) is called the "optical tube length." Weak and strong microscope objectives act differently. Weak systems act like photographic objectives. In this case the optical tube length may be altered within fixed limits, without spoiling the image; the same time the objective magnification is also altered. This change is usually effected by mounting the objective on a stage, and moving it. However, only one optical tube length in which it is possible to obtain a good image by means of wide pencils, any alteration of the system involves a considerable spoiling of the image. This limitation is examined below.

When forming an image by a microscope objective it often happens that the transparent media bounding the object have different optical properties. A series of objectives with short focal lengths are available, which permit the placing of a liquid between the cover-slip and the front lens of the objective; such lenses are known as immersion objectives. The objects are then imaged in the liquid phase and typical systems are bounded on both sides by air are called "dry systems." The immersion liquids in common use are water, glycerine, cedar-wood oil, monobromonaphthalene, &c. Immersion systems in which the embedding liquid, cover-slip immersion-lens and front lens have equal refractive indices are called "homogeneous immersion systems." In immersion systems the object-side focal length is greater than the image-side focal length. Nothing is altered as to objective magnification, however, as the first surface is plane, and the employment of the immersion means that the value of \( f' \) is unaltered.

If we assume that a normal eye observes the image through the eyepiece, the eyepiece must project a distant image from the real image produced by the objective. This is the case if the image \( O'O'' \) lies in the first focal plane of the eyepiece. In that case the optical tube length equals the distance between the adjacent focal planes of the two systems, which equals the distance of the image-side focus of the objective \( F_2 \) from the object-side focus of the eyepiece \( F_1 \) and the image viewed through the eyepiece appears then to the observer under the angle \( \tan \alpha = f'/2F \), and as with the single microscope,

\[
\tan \alpha = f'/2F \quad \text{or} \quad f'/2F = \tan \alpha
\]
To obtain the magnification of the complete microscope we must combine the objective magnification \( M \) with the action of the eyepiece. If we replace \( y \) in equation (4) by the value given by (3), we obtain
\[
\tan \theta' \cdot \frac{y}{l_1} = \frac{1}{f_1} \cdot M = V_1.
\]
the magnification of the complete microscope. The magnification therefore equals the powers of the joint system.

The magnification is also expressed as the ratio of the apparent size of the object observed through the microscope to the apparent size of the object seen with the naked eye. As the convention by a distance for clear vision with naked eye usually from fig. 1 that the apparent size is \( \tan \theta = y/l_1 \). If this value of \( y \) is inserted in equation (5), we obtain the magnification number of the compound microscope:
\[
N = \tan \theta' \cdot \frac{y}{l_1} = \frac{1}{f_1} \cdot M = V_1.
\]

The image produced by a microscope formed of two positive systems (fig. 13) is inverted, the objective \( L_2 \) tracing from the object \( O_0 \) a real inverted image \( O_0' \), and the eyepiece \( L_1 \) maintaining this arrangement. For many purposes, the eyepiece is inverted or upright; but in some cases an upright lightens the weight, or may be indispensable.

The simplest microscope negative lens as eyepiece.

**FIG. 14—Ray transmission in compound microscope with a negative eyepiece.**

\( L_1 \), \( L_2 \), \( F_1 \), \( F_1' \), \( F_2 \), \( F_2' \), \( P_1 \), \( P_1' \), \( P_2 \), \( P_2' \), \( Z \).

**FIG. 15.—Entocentric transmission through a microscope objective.**

\( E \)-plane focused for; \( O_1^*, O_2^* \) = projections of \( O_0, O_0' \) on \( E \); \( Z \) = centre of projection; \( P_1, P_1' \) = virtual image of real diaphragm \( P'P' \), with regard to the preceding part of the objective is the entrance pupil.

**FIG. 16.—Hypercentric transmission in a microscope objective.**

\( E \), \( O_1^*, O_2^* \), \( Z \) as in fig. 15. \( P_1 \) is the entrance pupil. The intersection of the principal rays lies in front of the objective, and consequently objects in front of the plane focused for will be projected on \( E \) magnified and the object lying behind it diminished ('hypercentric' transmission). It produces a perspective representation entirely opposed to ordinary magnification. As objects lying nearer to us, we receive a false impression of the spatial arrangement of the object.

Whether the entrance pupil be or behind the object, in general, its points can be placed in the objective, so that the principal rays will have in the objective space only trifling inclinations towards one another or are strictly parallel. This is specially important, for otherwise pencils from points placed somewhat laterally to the axis arrive with diminished aperture at the image.

We see from fig. 13 that the objective's exit pupil \( P'P' \) is portrayed by the positive eyepiece, the image \( P'P' \) limits the pencils.
PROCEEDING FROM THE EYEPIECE. This image $P'P''$ is then the exit pupil of the combined system, and consequently the image of the entrance pupil of the combined system. As the exit pupil $P'P''$ for the objective lies before the front focus of the eyepiece, generally at some distance from the eyepiece, the real image $I'$ does not lie behind the image-side focus of the eyepiece. The exit pupil, often called Ramsden's circle, is thus accessible to the observer, who by head- and eye-movements may survey the whole field.

We can now understand the transmission in the compound microscope, shown in fig. 13. Points of a small object (compared with the focus of the objective) send to the objective wide pencils. The diaphragm limiting them, i.e. the entrance pupil, is placed so that the principal rays are either parallel or at an angle with the pencils. The principal rays from a real image are very much more acute, and their inclination is the smaller the stronger the magnification. The eyepiece, which by means of narrow pencils represents the relatively large real image at infinity, transmits from all points of this real image only rays, whose inclination of the principal rays becomes further increased. The point of intersection, i.e. the centre of the exit pupil, is accessible to the eye of the observer. In the case of negative eyepiece, on the other hand, the inclination of the principal rays is not further augmented, but their point of intersection is not accessible to the eye. This property shows the superiority of the collective eyepiece over the dispersive.

The increase of the inclination of the principal rays, which arises with the microscope, influences the perception of the relief of the object. In entocentric transmission this phenomenon appears in general as in the case of the contemplation of perspective representations, as a too short distance in the appearance of objects after advantage. Although in the case of the spatial comprehension of a perspective representation experience plays a large part, in observing through a microscope it does not count, or only a little, for the object is primarily quite unknown. In the hypercentric transmission we obtain a false conception of the spatial arrangement of the objects or their details; in these cases fociuses by turns on the different details, and so obtains an approximate idea of their real arrangement.

While the limiting of the pencil is almost always effected by the objective, the limiting of the field of view is effected by the eyepiece, and indeed it is carried out by a real diaphragm $D$ arranged in the plane of the real image $O'Q'$ (fig. 13). The entrance window is then the real image of this diaphragm projected by the objective in the surface conjugate to the plane focused on, and the exit window is the image projected by the eyepiece; this happens with the image of the object lying at infinity. In this transmission we obtain a false conception of the spatial arrangement of the objects or their details; in these cases fociuses by turns on the different details, and so obtains an approximate idea of their real arrangement. The whole field of view is then the image of the eye of the observer, who by head- and eye-movements may survey the whole field. The rays from $O$ which have a greater inclination to the vertical than $48.75^\circ$ cannot come out into the air, but are totally reflected. If pencils proceed from media of high optical density to media of low density, and have a semi-aperture greater than the critical angle, total reflection occurs; in such cases no plane surface can be employed, hence front lenses have small radii of curvature. In order to permit the wide pencils to reach the air (see fig. 19, in which $P$ is the preparation, $O$ the object-point in it, $D$ the cover slip, $I$ the immersing liquid, and $L$ the front lens), the numerical aperture $n$ $\sin \phi$ of the objective has been called by Abbe the numerical aperture. In dry-systems only the sine of the semi-aperture is concerned; in immersion-systems it is the product of the refractive index of the immersion-liquid and the sine of the objective's semi-aperture. In the large objects obviously the whole pencil is involved, and hence the clearness is the squares of these values, i.e. $n^2\sin^2\phi$. As the semi-aperture of a pencil proceeding from an object point cannot exceed the semi-aperture of a pencil proceeding from an object point greater than $1$. On the other hand, in immersion-systems the numerical aperture can almost amount to the refractive index, for $A = \pi n < \frac{\pi}{\sin \phi}$.

The dispersive eyepiece, on the contrary, an almost unlimited field can arise, but vignetting must occur.

**Illumination.**—The dependence of the clearness of the image on the aperture of the system, i.e. on the angular aperture of the image-producing pencil, holds for all instruments.

The brightness of image points in a medium section of the pencil are proportional to the aperture of the lens, supposing that the rays are completely reunited. This is valid so long as the pencil is in air; but if, on the other hand, the pencil passes from air through a plane surface into an optically denser medium, e.g. water or glass, the pencil becomes thinner, and the apertures of the pencils in the image-producing pencils are lost in this transmission (apart from the slight loss due to refraction) the brightness of the image point in the water is as large as that in air, although the apertures have become less. Fig. 17 shows $N$, $n$, $w$, $w'$, $w''$, $w'''$, $u$, $u'$, then by the law of refraction $N \sin w = n \sin w'$, the value for the clearness in water is $N \sin w$. This rule is general. The value of the clearness of an image-point in a median section is the sine of the semi-aperture of the pencil multiplied with the refractive index of the medium through which the light passes.

An illustration of this principle is the immersion experiment.

A view taken under water from the point $O$ (fig. 18) sees not only the whole horizon, but also a part of the bed of the sea. The whole field of view in air of $180^\circ$ is compressed to one of $47.5^\circ$ in water. The rays from $O$ which have a greater inclination to the vertical than $48.75^\circ$ cannot come out into the air, but are totally reflected. If pencils proceed from media of high optical density to media of low density, and have a semi-aperture greater than the critical angle, total reflection occurs; in such cases no plane surface can be employed, hence front lenses have small radii of curvature. In order to permit the wide pencils to reach the air (see fig. 19, in which $P$ is the preparation, $O$ the object-point in it, $D$ the cover slip, $I$ the immersing liquid, and $L$ the front lens), the numerical aperture $n$ of the objective has been called by Abbe the numerical aperture. In dry-systems only the sine of the semi-aperture is concerned; in immersion-systems it is the product of the refractive index of the immersion-liquid and the sine of the objective's semi-aperture. In the large objects obviously the whole pencil is involved, and hence the clearness is the squares of these values, i.e. $n^2\sin^2\phi$. As the semi-aperture of a pencil proceeding from an object point cannot exceed the semi-aperture of a pencil proceeding from an object point greater than $1$. On the other hand, in immersion-systems the numerical aperture can almost amount to the refractive index, for $A = \pi n < \frac{\pi}{\sin \phi}$.

Dry systems of $0.98$ numerical aperture, water immersion $(n=1.53)$ from $A=1.25$, oil immersion $(n=1.51)$ from $A=1.40$, and even a-bromaphenalen immersions $(n=1.63)$ from $A=1.60$, are available. In immersion-systems of such considerable aperture no medium of smaller refractive index than the immersion liquid may be placed between the surface of the front lens and the object, as otherwise total reflection would occur. This is especially important in the case of electronic microscopy. As the optical path through the embedding and immersing liquids must have equal refractive indexes, one must use a-bromaphenalen for embedding; but this substance destroys organic preparations, so that one can employ the immersion-system only for examining inorganic materials, e.g. fine diatoms.

In immersion-systems a very much greater aggregate of rays is used in the representation than is possible in dry-systems. In addition to a considerable increase in brightness the losses due to reflection are avoided; losses which arise in passing to the back surface of the cover-slip and to the front surface of the front lens.

**The Physical Theory**

In order to fully understand the representation in the microscope, the process must be investigated according to the wave-theory, especially in considering the representation of objects or object details having nearly the size of a wave-length. The rectilinear rays, which we have considered above, but which have no real existence, are nothing but the paths in which the light waves are transmitted. According to Huygens's principle (see Diffraction) each aether particle, set vibrating by an incident wave, can itself act as a new centre of excitement, emitting a spherical wave; and similarly each particle on this wave itself produces wave systems. All systems which are emitted from a single source can by a suitable optical device be directed that they simultaneously influence one and the same aether particle. According to the phases of the vibrations at the point of their intersection, the particle is actuated in their action, and there arises greater clearness or obscurity. This phenomenon is called interference (q.e.). E. Abbe applied the Fraunhofer diffraction phenomena to the explanation of the representation in the microscope of uniformly illuminated objects.

If a grating is placed as object before the microscope objective, Abbe showed that in the image there is intermittent clear and dark banding only, if at least two consecutive diffraction spectra enter the objective. In principle and in practice this is the case only if the illuminating pencil is parallel to the axis of the microscope objective, the illumination is said to be direct. If in this case the aperture of the objective be so small, or the diffraction spectra lie so far from each other, that only the zero order can be admitted, no trace is generally found of the image of the grating. If, in addition to the principal maximum, the maximum of 1st order is admitted, the banding is distinctly visible and the object is represented only with one third of the clearness; but with 2nd order, the 2nd order spectrum is already sufficient to resemble the object. The resemblance is greater the more diffraction spectra enter the objective. From the Fraunhofer formula $d = \lambda n \sin \alpha$ one can immediately deduce the limit to the diffraction constant $d$, so that the illumination by an objective of fixed numerical aperture can be perceived. The value of $n \sin \alpha$ equals the numerical aperture $A$, where $n$ is the refractive index of the immersion-liquid, and $\alpha$ is the semi-aperture on the object-side. For microscopy the Fraunhofer condition is satisfied if we can admit only one spectrum without involving power in the case of direct lighting. All details of the object so resolved are perceived, if two diffraction maxima can be passed through the objective, so that the character of the object is seen in the image, even if an exact resemblance has not yet been attained.

The Fraunhofer diffraction phenomena, which take place in the...
MICROSCOPE

of direct lighting, so that a banding of double the fineness can be perceived. The illumination of the image is controlled by moving the diaphragm laterally. If the obliquity of illumination be so great that the principal maximum passes through the outermost edge of the objective, while a spectrum of 1st order passes over the opposite edge, so that in the back focal plane the diffraction phenomenon shown in fig. 22 arises, banding is still to be seen. The resolution in the case of oblique illumination is given by the formula \( A = \sin \alpha \).

Reverting to fig. 13, we suppose that a diffusing particle of such fine substance is placed at place \( O \) that the diffracted pencils of the 1st order make an angle \( \alpha \) with the axis; the principal maximum of the Fraunhofer diffraction phenomena lies in \( P' \); and the two diffraction maxima of the 1st order in \( P'' \). The waves proceeding from this point are united in the point \( O' \). Suppose that a well corrected objective is employed. The image \( O' \) of the point \( O \) is then the interference effect of all waves proceeding from the exit pupil of the objective \( P' \).

Abbe showed that for the production of an image the principal maximum must lie within the exit pupil of the objective. In the silverying of a glass plate series are ruled as shown in fig. 23, one traversing the field while the intermediate set extends only half-way across the aperture. If viewed in oblique lighting, so that the diffraction spectra of 1st order pass the inner divisions, then the corresponding diffraction phenomenon in the back focal plane of the objective has the appearance shown in fig. 21, while the diffraction spectra of 2nd order are as shown in the image fig. 20. If one cuts out by a diaphragm in the back focal plane of the objective all diffraction spectra except the principal maximum, one sees in the image a field divided into two halves, which show with different clearness, but no banding. By choosing a sufficiently large, broader diaphragm, so that the spectra of 1st order can pass the larger division, there arises in the one half of the field view the image of the larger division, the other half being clear without any such interference. By using an even wider diaphragm which at the spectra of 2nd order of the larger division and also the spectra of 1st order of the fine division, an image is obtained which is similar to the object, i.e. it shows bands one half a diagonal square as fine as on the other half. By increasing the order of the larger division it becomes possible to cut out from the interference figure, as is shown in fig. 24, an image is obtained which over the whole field shows a similar division (fig. 25), although in the one half of the object the represented banding does occur. Still more striking is this phenomenon shown by Abbe's diffusing plate (fig. 26) with a second order of diffracting formed by two perpendicular gratings. Through a suitable diaphragm in the back focal plane, banding can easily be produced in the image, which contains neither the vertical nor the horizontal lines of the two gratings, but there exist streaks, whose direction is the angle under which the two gratings intersect (fig. 27). There can thus be shown structures which are not present in the object. Colonel Dr. Woodward of the United States army showed that interference effects appear to produce details in the image which do not exist in the object. For example, two to five rows of globules were produced, and photographed, between the bristles of mosquito wings by using oblique illumination. In observing with strong systems it is therefore necessary cautiously to distinguish between spectral and real marks. To determine the utility of an objective for resolving fine details, one experiments with definite objects, which are usually employed simultaneously for examining other properties. Most important are the fine structures of diatoms such as Surirella gemma and Amphipleura lucida or artificial fine divisions as in a Nobert's grating. The examination of the objects can only be attempted when the different faults of the objective are known.

If microscopic objects are observed by diffused daylight or by the more or less white light of the usual artificial sources, then an objective of fixed numerical aperture will only represent details of a definite fineness. All smaller details are not portrayed. The formula gives the maximum for which the most useful magnification of such an objective in order to utilize its full resolving power.

As we saw above, the apparent size of a detail of an object must be greater than the angular range of vision, i.e. \( 1° \). Therefore we may assume that whether an angle of \( 2' \) can be seen. Supposing, however, there is oblique illumination, then formula (5) can always be applied to determine the magnifying power attainable with at least one objective. By substituting the size of the object, for \( d \), the smallest value which a single object can have in order to be analysed, and the angle \( w' \) by \( 2' \), we obtain the magnifying power and the magnification number:

\[
V = \tan w' = 2A \tan 2\beta; \quad N = 2A \tan 2\beta; \quad N_0 = 2A \tan 2\beta; \quad \text{where } \beta \text{ equals the size of } n = \frac{1}{2} \text{.}
\]

Even if the details can be recognized with an apparent magnification of \( 2\beta \), the observation may still be inconvenient. This may be improved when the magnification is so increased that the angle under which the object, when still just recognizable, is raised to \( 4' \).

The magnification and magnification number which are most necessary for the microscope with a given aperture can be calculated from the formulae:

\[
V = 2A \tan 4\beta; \quad N = 2A \tan 4\beta; \quad N_0 = 2A \tan 4\beta.
\]

If \( d = 55 \mu \) is assumed for daylight observation, according to Abbe (Journ. Roy. Soc., 1882, p. 493) we have the following table for the limits of the magnification numbers, for various microscope objectives:

\[
A \approx \sin \alpha = \frac{d}{2A} \sin \beta = \frac{d}{2A} \tan \beta = \frac{d}{2A} \tan 2\beta.
\]

From this it can be seen that, as a rule, quite small magnifications suffice to bring all representable details into observation. If the magnification is below the given numbers, the details can either not be seen at all, or only very indistinctly; if, on the contrary, the given magnification is increased, there will still be no more details visible. The table shows at the same time the great superiority of the immersion-system over the dry-system with reference to the resolving power. For example, in an immersion system, having a numerical aperture of 1-6, details of the size 0-17 \( \mu \) can be resolved, while the theoretical maximum of the resolving power is 0-167 \( \mu \), so that the theoretical maximum has almost been reached in practice. Still smaller particulars cannot be portrayed by using ordinary day-light.

In order to increase the resolving power, A. Köhler (Zeit. f. Mikros. 1904, 21, pp. 129, 273) suggested employing ultra-violet light, of a wave-length 275 \( \mu \mu \); he thus increased the resolving power about double that which is reached with day-light, of which the mean wave-length is 550 \( \mu \mu \). Light of such short wave-length is, however, not visible, and therefore a photographic plate must be employed. Since glass does not transmit the ultra-violet light, a photographic glass is used, but such glasses can only be spherically corrected and not chromatically. For this reason the objectives have been called monochromats, as they have only been corrected for light of one wave-length. Further, the different transmission of the ultra-violet rays of the same wave-length causes the necessity of dyed the preparations. Glycerin is chiefly used as immersion fluid. M. v. Rohr's monochromats are constructed with apertures up to 1-25. The smallest resolving detail with oblique lighting is: \( V = 2A \tan 2\beta = 275 \mu \mu \). The microscopist usually estimates the resolving power according to the so-called ordinary day-light, Köhler introduced the "relative resolving power" for ultra-violet light. The power of the microscope is thus represented by supposing day-light with a wave-length of 550 \( \mu \mu \). Then the denomination of the numerical aperture number remains, but may be correspondingly increased, in order to ascertain the real resolving power. In this way a monochromat for glycerin of a numerical aperture 1-25 gives a relative numerical aperture of 2-50. If the magnification be greater than the resolving power demands, the observation is not only needlessly made more difficult, but the entrance pupil is diminished, and it with a very considerable decrease of clearness, for with an objective of a certain aperture the size of the exit pupil depends upon the magnification. The diameter of
The exit pupil of the microscope is about 0.04 in. with the magnification \( N_3 \) and about 0.02 in. with the magnification \( N_4 \). Moreover, with such exceptionally narrow pencil shadows are formed on the retina of the observer’s eye, from the irregularities in the eye itself. These disturbances are called Kerbeck’s aberrations. With the section Regulation of the Rays (above) it is seen that the resolving power is opposed to the depth of definition, which is reciprocal of the numerical aperture, \( r/A \).

Dark-field Illumination.—It is sometimes desirable to make the most of objects in a preparation specially visible. This can be done by cutting off the chief maximum and using only the diffracted spectra for producing the image.

At least two successive diffraction maxima must be admitted through the objective for there to be any image of the objects. With this device these particles appear bright against a dark background, and can be easily seen. The cutting off of the chief maximum can be effected by a suitable diaphragm in the back focal plane of the objective. But, owing to the various partial reflections which the illuminating cone of rays undergoes when traversing the surfaces of the objective, the portion of the light comes again into the preparation, and into the eye of the observer, thus veiling the image. This defect can be avoided (after Abbe) if a small central portion of the back surface of the front lens be ground away and blackened; this portion should exactly catch the direct cone of rays, whilst the edges of the lens let the deflected cone of rays pass through (fig. 28).

The large loss of light, which is caused in dark-field illumination by the cutting off of the direct cone of rays, must be compensated by employing exceptionally strong sources. By dark-field illumination it is even possible to make such small details of objects perceptible as are below the limits of the resolving power. It is a similar phenomenon to that which arises when a ray of sunlight falls into a darkened room. The extremely small particles of dust (notes in a sunbeam) in the rays are made perceptible, and can be easily seen. The cutting off of the chief maximum is therefore an advantageous feature, for the eye is now able to see a part of it, which has hitherto been invisible. The same observation can be made with the cone of rays of a reflector, and in the same way the fine rain-drops upon a dark background, and the fixed stars in the sky become visible. It is not possible to recognize the exact form of the minute objects, because their apparent size is much too small; only their presence is observable. In addition, the particles can only be recognized as separate objects if their apparent distance from one another is greater than the angular definition of sight.

Ultramicroscopy.—This method of illumination has been used by H. Siedentopf in his ultramicroscope. The image consists of a diffraction disk from whose form and size certain conclusions may be drawn concerning the resolution power of the objective.\(^4\) With the micrometer, as for the microscope, there is nothing to gain in this respect. The method is particularly valuable in the investigation of colloidal solutions. Siedentopf employed two illuminating arrangements. With the orthogonal arrangement for illuminating and observing the beam of light traverses an extremely fine slit through a well-corrected system, whose optic axis is perpendicular to the axis of the microscope; the system reduces the dimensions of the beam to about 2 to 4 \( \mu \) in the focal plane of the objective. For the microscopical observation the image is then resolved in a very small area by the objective. For the micrometer observation, the image is reduced by lowering the microscope to the objective, and the micrometer is read from the eyepiece. With suitable dark-field screens, that no direct rays enter the observing system. The only sources of light are sunlight or the electric arc.

The limit at which under-microscopic particles are made visible is determined by the intensity of the sources. With sunlight particles can be made visible to a size of about 0.004 \( \mu \).

Production of the Image.—As shown in LENS and aberration, for reproduction through a single lens with spherical surfaces, a combination of the rays is only possible for an extremely small angular aperture. Moreover, an enormous number of rays are needed, so that no deflections can be recorded at once, until the elimination, or a sufficient diminution of the spherical and chromatic aberrations has been brought about.

The objective and eyepiece have such different functions that as a rule it is not possible to control the aberrations caused by those of the other. Such a compensation is only possible for one single defect, as we shall see later. The demands made upon the eyepiece, which has to represent a relatively large field by narrow cones of rays, are not to be regarded as very considerable. It is therefore not very difficult to produce a usable eyepiece. On the other hand, the correction of the objective presents many difficulties.

We will now examine the conditions which must be fulfilled by an objective, and then how far these conditions have been met.

Consider the aberrations which may arise from the representation by a system of wide aperture with monochromatic light, i.e. the spherical aberrations. The rays emitted from an axial object-point are combined into one image-point by an ordinary biconvex lens of fixed aperture, but the central rays come to a focus closer than the outer rays. The so-called "caustic" occupies a definite position in the image-space. The spherical aberrations, however, may be overcome, or at least so diminished that they are quite harmless, by forming appropriate tangential and axial curves.\(^4\)

The aberration of rays in which the outer rays intersect the axis at a shorter distance than the central rays is known as "under-correction." The converse is known as "over-correction." By selecting the radius of the surfaces and the kind of glass, or over-correction can be regulated. Thus it is possible to correct a system by combining a convex and a concave lens, if both have aberrations of the same amount but of opposite signs. In this case the power of the crown lens must preponderate so that the cutting of light is of the same sign, but of a little less power. Correction of the spherical aberration in strong systems with very large aperture can therefore with a single combination of two lenses, be applied to the objective. Under-corrected systems must be combined with over-corrected ones.

Another way of correcting this system is to alter the diameters. If by these methods, a point in the optic axis has been freed from aberration, it does not follow that the whole distance of light from the optic axis can be represented without spherical aberration. The representation, free from aberration, of a small surface-element, is only possible, as Abbe has shown, if the object is at a distance of a very large number of focal lengths, the ratio of the sine of the aperture \( u \) on the object-side to the sine of the corresponding aperture \( u' \) on the image-side being constant, \( i.e. \tan u/\tan u' = C \), in which \( C \) is a constant. The sine-condition is therefore regarded as the point-by-point representation of the whole object in the image-space (see Lens), and according therefore the equation \( \tan u/\tan u' = C \) must exist.

These two conditions are only compatible if the representation is made with quite narrow pencils, and where the aperture is so small that the sines and tangents are of about the same value.

Very large apertures occur in strong microscope objectives, and hence the two conditions are not compatible. The sine-condition with a magnification of 1,000 is of no importance, as for the microscope, the most important to consider when the microscope is concerned, because it must be possible to represent a surface-element through the objective by wide cones of rays. The removal of the spherical aberration and the sine-condition can be accomplished only by employing two or more conjugate lenses. In this way, a combination with a wide aperture therefore can only represent, free from aberrations, one object-element situated on a definite spot on the axis. As soon as the object is moved a short distance away from this position, the sine-condition is quite useless. H. N. F. Kehl has shown of observing the length of the tube in strong systems. If the sine-condition is not fulfilled but the spherical aberrations in the
MICROSCOPE

axis have been removed, then the image shown in fig. 19 results. The cones of rays issuing from a point situated only a little to the

Fig. 29.—The lens is spherically corrected for OO', but the sine-condition is not fulfilled. Hence the different magnifications of a point O, beyond the axis, which traverse different zones of the objective, have a different magnification. The sine-condition can therefore also be understood as follows: that all objective zones must have the same magnification for the plane-element.

According to Abbe, a system can only be regarded as aplanatic if it is spherically corrected for not only one axial point, but when it also fulfils the sine-condition, and thus magnifies equally in all zones a surface-element situated vertically on the axis at this point.

A second method of correcting the spherical aberration depends on the condition that, if there are two transparent substances separated from one another by a spherical surface, then there are two points on the axis where they can be reproduced free from error by monochromatic light, and these are called "aplanatic points." The first is the centre of the sphere. All rays issuing from this point pass unrefracted through the dividing surface; its image-point coincides with it. Besides this there is a second point on the axis, from which all issuing rays are so refracted at the surface of the sphere that, after the refraction, they appear to originate from one point—the image-point (see fig. 30). With this, the object-point O, and consequently the image-point O' also, will be at a quite definite distance from the centre. If however the object-point does not lie in the medium with the index n, but before it, and the medium is, for example, like a front lens, still limited by a plane surface, just in front of which is the object-point, then in traversing the plane surface spherical aberrations of the under-corrected type again arise, and must be removed. By homogeneous immersion the object-point can readily be reduced to an applanatic point. By experiment Abbe proved that old, good microscope objectives, which by mere testing had become so corrected that they produced usable images, were not only free from spherical aberrations, but also fulfilled the sine-condition, and were therefore really aplanatic systems.

The second aberration which must be removed from microscope objectives are the differences of these aplanatic lenses of crown-glass is combined with a dispersing lens of flint; in such a system the red and the blue rays intersect at a point (see ABBERRATION). In systems employed for visual observation (to which class the microscope belongs) the red and blue rays, which include the physiologically most active part of the spectrum, are combined; but rays other than the two selected are not united in one point. The transverse sections of these cones of rays diverge more or less from the transverse section of the chosen red and blue cones, and produce a secondary spectrum in the image, and the images still appear to have a slightly coloured edge, mostly greenish-yellow or purple; in other words, a chromatic difference of the spherical aberrations arises (see fig. 31). This refers to systems with small apertures, but still more so to systems with large ones; chromatic aberrations are exceptionally increased by large apertures.

The new glasses produced at Schott's glass works, Jena, possessed in part optical qualities which differed considerably from those of the older kinds of glass. In the old crown and flint glass a high refractive index was always connected with a strong dispersion and the reverse. Schott succeeded, however, in producing glasses which with a comparatively low refraction have a high dispersion, and with a high refraction a low dispersion. By using these glasses and employing minerals with special optical properties, it is possible to correct objectives so that three colours can be combined, leaving only a quite slight tertiary spectrum, and removing the spherical aberration for two colours. Abbe called such systems "apochromats." Good apochromats often have as many as twelve lenses, whilst systems of simpler construction are only achromatic, and are therefore called "achromats."

Even in apochromats it is not possible to entirely remove the chromatic difference of magnification, i.e. the images produced by the red rays are somewhat smaller than the images produced by the blue. A white object is represented with blue streaks and a black one with red streaks. This aberration can, however, be successfully controlled by a suitable eyepiece (see below).

A further aberration which can only be overcome with difficulty, and even then only partially, is the "curvature of the field," i.e. the points situated in the middle and at the edge of the plane object cannot be seen clearly.

Historical Development.—The first real improvement in the microscope objective dates from 1830 when V. and C. Chevalier, after the designs of Sellier, produced objectives, consisting of several achromatic systems arranged one above the other. The systems could be used separately or in any combination. A second method for diminishing the spherical aberration was to alter the distances of the single systems, a method still used. Sellier had no particular comprehension of the problem, for his achromatic single systems were simply telescope objectives corrected for an infinitely distant point, and were placed so that the same surface was turned towards the object in the microscope objective as in the telescope objective; although contrary to the telescope, the distance of the object in the microscope objective is small in proportion to the distance of the image. It would have been more correct to have employed these objectives in a reverse position.

These circumstances were considered by Chevalier and Lister. Lister showed that a combination of lenses can be achromat for only one system on the axis, the systems must be so arranged that the spherical wave-point of the first system coincides with the object-point of the next system. This system will always be spherical wave-points; the spherical aberrations permitted a much larger aperture than a simple achromatic system. Although such systems have been made recently for special cases, in this case the single lenses of the single objective are abandoned, and a more complex one adopted, which also made the production of better objectives possible; this is the principle of the compensation of the aberrations produced in the different parts of the objective. Even Lister, who profited on quite and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to diminish the spherical aberration of the objective, and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to diminish the spherical aberration of the objective, and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to diminish the spherical aberration of the objective, and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to diminish the spherical aberration of the objective. Amici employed cemented pairs of lenses consisting of a plano-convex flint lens and a biconvex crown lens (fig. 32), and although the objective was of a very small aperture, he showed that the influence of the cover-slip on pencils of such wide aperture. The lower surface of the slip causes under-correction on being traversed by the pencil, with over-correction where the slip leaves it; and since the eye is lying flatterest from the object, i.e. those caused by the upper surface preponderate, an over-corrected cone of rays enters the objective. The over-correction increases when the glass is thickened. In order to counteract this under-correction, it is necessary to have the thickness of the glass cover on either side of the objective. Objectives with definite under-correction can however only produce really good images with glass covers of a specified thickness. With apertures of 0-90-0-95 degrees, the image can be noticed by the deterioration of the image. In systems with smaller apertures, variations in the thickness of the glass cover are not so
noticeable. For this reason Amici constructed objectives of a similar aperture and focus for different thicknesses of glass covers. This expensive method was simplified in 1837 by Andrew Ross by making the upper and lower portion of the objective variable by means of a so-called correction-collar, and so giving the objective a correcting under-correction according to the thickness of the glass cover. The alteration of the focus and the aperture are little influenced. The correction-collar was improved by Wenham and Zeiss, by working the upper system upon the lower, and not the reverse for in this way the preparation remains almost entirely focused during the operation (see fig. 34).

The injurious influence of the glass cover is substantially lessened if no air is admitted to the space between the glass cover and the front lens (as in the dry-system) but if the intervening space is filled with an immersion-liquid. Amici was likewise the first to produce practical and good immersion-systems. The slight difference of the refractive indexes of the glass cover and the immersion-liquid involves a diminution of the aberrations, by which the objective will become less sensitive to the differences in thickness of the glass covers and admits of a more perfect adjustment. Water-immersion was introduced by Amici in 1840, and was improved by E. Hartnack in 1855.

The advantages of the immersion over the dry-systems are greatest when the embedding-liquid, the glass cover, the immersion-liquid and the front lens have the same refractive index. Such systems with a so-called homogeneous immersion were first constructed after the plan of E. Abbe in 1878 by Dr. F. A. Zieg, at the instigation of J. W. Stephenson. Cedarwood oil (canada balsam), which has a refractive index of 1.515, is the immersion-liquid. The structure of a modern system of this type, with a numerical aperture of 1:30, is shown in fig. 35.

The most perfect microscope objective was invented by E. Abbe in 1886 in the so-called apochromatic objective. In this, the secondary spectrum is so much lessened that for all practical purposes it is unnoticed. In the apochromats the chromatic difference of the spherical aberration is eliminated, for the spherical aberration is completely avoided for three colours. Since in these systems the sine-condition can be fulfilled for several colours, the quality of the images of points beyond the axis is better. There still remain a slight chromatic difference in magnification, for although the magnification consequent upon the fulfilment of the sine-condition is the same for all zones for one colour, it is impossible to avoid a change of the magnification with the colour. Abbe overcome this defect by using the so-called compensation ocular, made with Jena glasses. Fig. 36 shows an apochromat of a numerical aperture of 1:40.

**THE EYEPIECE OR OCULAR**

The eyepiece is considerably simpler in its construction than the objective. Its purpose in a microscope is by means of narrow cones of rays to represent at infinity the real magnified image which the objective produces. As, however, the object represents a real image, the problem is to project a transparent diapositive. It is therefore impossible to observe this image through an ordinary lens. Since many of the rays coming from the exit-pupil of the objective would not reach the eye of the observer at all, it is necessary, in order to make use of them, to direct the diverging rays forming the real image so that the whole of the light enters the eye of the observer. This is effected by a collective lens; it may be compared with the second part of the condenser system of a projecting lantern.

The two most customary eyepieces consist in two simple plano-convex lenses, whose distance one from the other is equal to half the sum of the two focal lengths. One of these is the Ramsden eyepiece (fig. 37). If the real image produced by the objective coincides with the collective lens, only the inclination of the principal rays is altered, the form of the cone being affected only to a very small extent. The lens nearer the eye, which has about the same focal length as the collective lens, is distant from it by about its focal length. The eye-lens converts diverging pencils into parallels. Both lenses together form the exit-pupil of the objective behind the eye-lens, so that this image, the exit-pupil of the total system or the Ramsden circle, is accessible to the eye of the observer. It is possible to see the whole field through this pupil by slightly moving the head and eye. In practice the real image is formed not directly on the collective lens but a little in front of it, because otherwise all the particles of dust on the collective would also be seen magnified.

In the type, the Huygenian eyepiece (fig. 38), which is much more widely used, the collective lens is in front of the real image; it alters the direction of the principal rays and somewhat diminishes the real image. In this type the eye-lens is about twice as powerful as the collective lens, and makes the rays parallel. Here also the exit-pupil is accessible to the eye and through it the whole field can be seen by moving the head and eye. In both eyepieces micro-meters or cross-wires are used for measuring in the plane of the real image. The Ramsden eyepiece is the most convenient for this because this plane lies in front of the collective lens, and the objective image has not to be affected by the eyepiece. As both eyepieces are used with very small apertures (about f: 20) no attempt has been made to overcome the spherical aberrations, which are usually very slight; neither, as a rule, are the eyepieces chromatically corrected, care has only to be taken by a suitable choice of the distance of one lens from the other, that the coloured images derived from a colourless object should have the same apparent size. Since, however, the difference of chromatic magnification cannot be overcome in powerful objectives, this error is still further increased by the eyepiece. The difference of chromatic magnification cannot even be overcome in apochromats, and to cancel this aberration Abbe devised the compensation ocular (fig. 39).

The weak compensation oculars resemble a Huygenian eyepiece with achromatic eye-lens, whilst the more powerful ones are of a different construction. These eyepieces are intentionally provided with a different chromatic magnification, which however is in opposition to that originating in the objective. They have also a shorter focal length. These eyepieces are very convenient in use, for when they are changed the lower focus always falls in about the same plane. In German and French microscopes the optical length of the tube, when apochromats and compensation-eyepieces are used, is 180 mm. By multiplying the magnification of the objective by the number of...
on the eyepiece the total magnification of the microscope is obtained. By the magnification of the objective is meant the ratio of the distance of distant vision to the focal length of the objective. As powerful achromat objective shows differences of chromatic magnification in the same way as aperplan or apochromat eyepieces can be used in combination with these objectives.

Illuminating Systems

Most microscopic observations are made with transmitted light; an illuminating arrangement is therefore necessary, and as the plane of the object is nearly always horizontal or only slightly inclined, the illuminating rays must be directed along the optical axis of the microscope.

To fully utilize the aperture of the system all dispersing rays in the object-space of the objective must be retained in the image-space of the illuminating system. When this occurs the greatest brightness will be obtained if the corresponding diaphragms of the two systems coincide, i.e. the field-diaphragm on the object-side of the observing system with object-side of the illuminating system, and the exit pupil of the illuminating system with the entrance pupil of the objective.

For slight magnifications a revolving plane mirror fixed below the object for altering the direction of the rays suffices. For this mirror to illuminate all the points of the objective so that the rays fill up the objective, it must not be too small, and should be as near as possible to the stage plate, and the source of light must be considerably extended (fig. 40). Diffused daylight is very suitable. If the aperture of the objective is increased, the diameter of the illuminating surface must also be increased so that the system is quite filled up, from which it follows that this method of illuminating soon fails. The possibilities of illuminating with a concave mirror seem a little more favourable. As a rule a concave mirror of similar aperture is fitted on the other side of the plane mirror. With the concave mirror an image of the source of light can be thrown upon the object. The distance of the concave mirror from the stage plate is about equal to its focal length. This is also the most suitable distance when diffused daylight is used, but it is too short with artificial light; the distance between the stage plate and the mirror should then be increased, so that an image of the source of light can be thrown upon the object. It is simpler to place an illuminating lens in front of the source of light so that the illuminating cone falls at the front focus of this lens and consequently is represented at infinity through the illuminating lens. By a correct choice of the focal length of the illuminating lens in relation to the focal length of the mirror, it is possible to choose the size of the image of the source of light so that the whole object-field is uniformly lighted.

Too much light is useless for observing delicately coloured or colourless preparations, whose parts only become visible by a small of slightly different diffusions of light. Then it is necessary to make use of powerful concentrated cones of light. The apparatus must be such that the apertures of the illuminating rays can easily be altered, e.g. by inserting a diaphragm. The rays of the illuminating cone below the stage plate (fig. 40, PP). This concentration of rays is mostly achieved by sliding or revolving diaphragms. A series of holes of different sizes perforate a revolving disk below the stage plate at an equal radial distance from the axis of the disk, so that the holes can be brought under the preparation in turn, the centre of the diaphragms always being a continuation of the optical axis of the microscope.

The so-called cylinder diaphragms (fig. 41) are used especially in German microscopes. A changeable diaphragm is placed at the upper end of a short tube which can be moved in a case below the stage in the direction of the optical axis (fig. 41). By bringing the diaphragm nearer the object the aperture of the rays is increased; if the diaphragm is removed the cone of rays is diminished (cf. fig. 40). These diaphragms are sometimes fitted in a slide, so that it is possible to move the diaphragm sideways and give oblique illumination (see below).

With very powerful objectives these methods are insufficient; and a condenser is fitted below the stage plate. As a rule an iris diaphragm, which can be moved sideways, is now fitted below this condenser; below is the mirror which can be moved in all directions. The Abbe apparatus consists of a condenser, movable iris diaphragm, and mirror (fig. 42). The whole apparatus can be focused by a rack and the button \( k \). The iris diaphragm can be regulated by the lever \( f \); it can also be turned to one side round the pivot \( a \), so that the condenser \( k \) can be removed or changed. The correct direction can be given to the illuminating cone by the mirror \( m \). It is often desirable to pass from direct to oblique lighting. The Abbe apparatus makes this easy. The iris diaphragm is pushed to the side by the rack and pinion \( n \). The chief cone of rays then enters obliquely into the objective, the angle between the direct cone of rays and the dispersion spectrum of the first order can then become as large as again as with direct lighting, and still be taken up in the objective. Oblique lighting, however, can only be in an azimuth, so that the object must be turned in order that the details may be observed. Hence a condenser, for lighting with very oblique cones, must have about the same aperture as the objective, and therefore be of very wide aperture; they therefore closely resemble microscope objectives in construction. Especially powerful achromatic condensers are really only magnified microscope objectives, with the difference that they are not corrected for the thickness of the cover slip, but for the thickness of the glass on which the object is placed. For exceptionally accurate work microscope objectives are sometimes used as condenser systems. When using immersion objectives, an immersion condenser must also be used if rays of extreme obliquity are wanted, for, in consequence of the total reflections, rays can only come from the upper surface of the condenser, which have not a larger inclination to the axis than about 41°, varying according to the refractive index of the glass. In order to let highly inclined rays pass out from the condenser, some immersion liquid must be placed between the upper surface of the condenser and the object slide. Condensers are for this reason also constructed with apertures up to 4-6.

Vertical Illuminators,—Opaque objects can only be seen by reflected light. With low magnifying systems and a large free object distance, ordinary good daylight is sufficient. If the objects have a low reflecting power, or if a slightly higher magnification is needed, the lighting can be improved by optical system.

To examine small opaque objects with a high magnification the Lieberkühn mirror, so named after its inventor, was formerly much used. This was a concave mirror, pierced in the middle, fixed to the objective, and directed towards the object and with such a
focal length that rays parallel to the axis falling upon it were united exactly upon the object. In this case the object lay upon a stage plate, whose centre had so far been made opaque, so that the rays coming from the illuminating plane mirror could not reach the objective directly, but only the rays passing through the stage plate to the side of this blackened portion reached the Liebkehln mirror, and were used in lighting. The disadvantage of this method was that only small opaque objects could be examined. Much more easily manipulated is the parabolic side-illuminator invented by R. Beck, which can be conveniently fitted in and used for objectives with different focal lengths. It consists in half of a short focused parabolic mirror, which concentrates all the light coming from the one side on to the objective, to examine object with objectives of high positive and low free object distance, the apparatus for side-illumination is not sufficient, and a so-called vertical illuminator is used. In Zeiss's form (fig. 43) a small prism \( p \), which also revolves upon a horizontal axis, is made near as possible to the back lens of the objective. The edge which is the separating line of the horizontal and hypothemuse surfaces of the prism, lies approximately over the middle of the system, so that the rays entering through the opening in the side after having been reflected by the hypothemuse surface are concentrated through one half of the objective on to the object. When observing only the other half of the objective is used. The sources of light used should be arranged so that the objective throws an image of the light-source upon the object. It is best if the image of the light is not larger than the object examined, and to effect this, an illuminating lens with an iris diaphragm is often placed between the source of light and the illuminator. By suitable adjustment and by changing the iris diaphragm the size of the illuminating field can be controlled. The objects observed with the vertical illuminator must not have a glass cover if the dry surface, and the direct reflection to the objective should be prevented; one would send so much light back into the objective by reflection, that the image would be indistinct. It is, on the contrary, possible to examine covered objects with the vertical illuminator, if the immersion medium be employed. Owing to the slight difference of illumination between the immersion liquid and the cover, the portion of light reflected on the cover is not noticeable.

**Dark Field Illumination.**—As was seen when discussing the physical theory, the minute details of the object cause diffractions, and can only be examined if the objective can take up at least two consecutive diffraction spectra. These diffracting details become especially distinct if the direct lighting cone of rays, the spectrum of zero order or the chief maximum, is not allowed to enter the objective, and instead only two or more diffraction maxima are taken up: the details then appear bright on a dark background. In dark field illumination care has to be taken that no direct rays reach the objective, and hence a good dark condenser system has a larger aperture than the objective. If an Abbe lighting apparatus is used a dark field diaphragm (fig. 44) can be placed in the iris diaphragm case. The central disc, which keeps the rays as much as possible from entering the diaphragm and otherwise fall directly into the objective, and the open zones sends so many oblique rays through the object that they cannot all be taken up by the objective. Exactly the same effect is reached when, as is shown in fig. 45, a more powerful system D is used for a condenser, which has a blackened section on the back of the front lens of such a size that no light can enter the objective A. In this way it is only possible for diffracted rays to enter the objective.

Apparatus of the kind has received much attention, because in this way ultra-microscopical particles can be made visible. This depends on the good combination of the entering cones of rays, which should be as oblique as possible: this is most easily done by using wide-angle condensers. A number of early inventions have been revived for this purpose.

Wenham's paraboloid illuminator (fig. 46) is made entirely of glass, and is in the form of a paraboloid, having on the top a spherical hole, of which it is arranged that all rays passing through this right, parallel to the axis, after their reflection on the surface of the paraboloid, traverse the spherical surface perpendicularly and unite in F, the centre of the sphere. A diaphragm \( s \) is placed in the middle of the spherical surface, and this back the central rays are sometimes fixed to a handle piercing the condenser, and which can be moved up and down, so that the aperture of the oblique entering cones of rays can be altered. Another form of the paraboloid condenser, also due to Wenham, has a plane surface on the upper side. Some immersion fluid must then be placed between the stage plate and the condenser in order to allow all the rays to pass out; otherwise only those rays would be able to pass out which are close to the axis of the condenser in the inside of the condenser, and are smaller than the limit of the total reflection.

**FIG. 45.—Path of Rays for dark-ground illumination with fixed diaphragm in the objective.**

(Objective D can also be used as a condenser (Zeiss).)

Th. Ross's "spot lens," invented in 1855, and J. W. Stephenson's catoptric illuminator (1879), may also be mentioned. A recent condenser of very high illuminating power is due to H. Siedentopf (fig. 47). It is a double mirror system, whose reflecting surfaces are a sphere \( a \) and a cardioid \( b \). The combination of rays is also sufficient in practice if the cardioid surface is replaced by a spherical one.

**FIG. 46.—Wenham's Paraboloid Condenser.**

A supplementary spherical surface \( c \) is necessary for the completion of the condenser.

**FIG. 47.—Siedentopf's Cardioid Condenser.**

**Binoocular Instruments**

The stereo-microscope is the most suitable for finding out the space taken up by the separate parts of a preparation. (See also Binoocular Instruments and Stereoscopy.) The observer has a stereoscopic impression of an object, when different perspective representations are presented to both eyes, which, through the action of the central nervous system, resolve into one impression.

One way of receiving a stereoscopic impression through a microscope is by fixing an apparatus as directly as possible above the last lens of the microscopic objective, which divides the rays passing out and directs half into each eye-piece. The half cones of rays have now semicircular sections, the diaphragms having the same form. The cones must be so directed through the divided system that the two exit pupils correspond to the interpupillary distance of the observer. The distance of the pupils back the central rays is sometimes fixed to a handle piercing the condenser, and which can be moved up and down, so that the aperture of the oblique entering cones of rays can be altered. Another form of the paraboloid condenser, also due to Wenham, has a plane surface on the upper side. Some immersion fluid must then be placed between the stage plate and the condenser in order to allow all the rays to pass out; otherwise only those rays would be able to pass out which are

systems of wide aperture. On account of the slight depth definition, short focused systems of wide aperture are not at all specially suitable for stereoscopic observation, because the possibility of observing objects taking a good deal of space is too limited when such systems are used.

Professor J. L. Riddell (Quart. Journ. Micro. 1853, p. 236; 1854, pp. 18–24) published an arrangement of prisms, which, however, imparted a pseudomorphous impression if image-forming oculars were not used. In 1854 a second system (fig. 48), essentially a Wheatstone pseudoscope, added just above the objective. This gave an orthoscopic image even in ordinary eyepieces. By adopting right-angled prisms above the objective he completely erected the image. Stephenson’s stereoscopic microscope (fig. 58, Plate) resembles this apparatus in all essentials. A construction of prisms by Nachet is now almost forgotten, while on the contrary an extremely simple dividing prism published by Wenham (London, 1854) has been exceptionally well attested in practice. It is now used on any other apparatus (see Binocular Instruments, fig. 8). A reflecting prism in fig. 49 is a setting placed above the last surface of the objective and divides the exit rays. The group of rays coming from the left half of the objective can hardly have hindrance to the right eye. The group of rays coming from the right half of the objective is reflected twice in the prism and directed to the left eye. The tube containing the objective is a little inclined towards the right tube, which is placed a little behind the tube and can be adapted to the interpupillary distance by changing the tube slide. If it is desired to use the instrument as a monocular, the setting with the prism at the lower end of the tube is taken away.

Fig. 48.—Riddell’s Prisms.

Fig. 49.—Wenham’s Prisms.

The second manner of making stereoscopic observations employs stereoscopic eyepieces. The first of such eyepieces was proposed by R. B. Tolles. He realized that the division of the cones of rays by prisms could only be satisfactorily performed if the prism was placed in the exit pupil of the objective or in the most distant portion of the real image of this exit pupil. He employed a Nachet combination of prisms and placed the dividing prism at the point where a special reversing system formed a real image of the exit pupil of the objective. This second stereoscopic eyepiece was devised by A. Przamowski who substituted a Wenham diffracting division prism at the position of the real image of the exit pupil of the objective formed by a reversing system. The newest form of a stereoscopic microscope resembles in all essentials the forms of Wenham’s microscopes. In the youngest microscope by Cherubin d’Orleans the observer receives a pseudoscopic impression in consequence of the reversed image. This defect has been avoided in the microscope constructed in the Zeiss factory (fig. 59, Plate) at the instigation of the American zoologist H. S. Greenough. The system of Porro prisms employed affords a convenient method of adapting the ends of the eyepieces to the interpupillary distance. The eyepieces are inclined to one another at an angle of 2°. The microscope is only intended for slight magnifications. The possibility already suggested of using both eyes for observing without having a stereoscopic impression, is often regarded as a great advantage. Binocular eyepieces are not constructed on this plan. Such a combination of prisms was used by Wenham, who placed it directly behind the last objective lens. As a rule all arrangements of prisms can be exchanged for the Wenham stereoscopic eyepiece.

A second kind of dividing prism which directs the entire course of rays to both eyes, and thus produces identical images, was used by Powell and Lealand (fig. 50). Every ray is divided into a reflected and a refracted portion on the front face of a parallel plate. Whilst the refracted portion, after leaving the plane plate continues its way in the same direction, displaced a little to one side, the reflected portion is directed into the side tube by a reflection-prism. With these microscopes, which are not stereoscopic, objectives of any power can be used. The surfaces of the dividing prisms must be very exact, so that any deterioration of the image may arise from them. A microscopic effect is obtained by employing the Abbe stereoscopic eyepiece. By the supplementary use of one of Wenham’s prisms every ray is analysed into a more powerful and weaker reflected ray which can be presented to each eye by using this eyepiece also. No stereoscopic impression is then felt. It is brought about by placing special semicircular diaphragms in the plane of the exit pupil of the microscope.

Fig. 50.—Powell’s Prisms.

Turning the diaphragms 180° round the optical axis, the orthoscopic impression can be changed into the pseudoscopic. The mechanical arrangement of the eyepiece is such that the distance of the two exit pupils can be adjusted to the interpupillary distance.

Mechanical Arrangements

Although the optical system is the first consideration in a microscope, the system is valueless if the fittings do not allow its correct use. The optical system must be kept at a certain distance and well centred, and a correct position for the object in relation to the system must be assured.

In fig. 60, Plate, the microscope is seen to consist of the heavy metal foot A, which rests on the table at three points. The whole microscope is fitted to this foot. The object can be held firmly on the stage plate B by clamps C. On the lower side of the stage plate are the condenser and the diaphragms, and the illuminating mirror J is held by a rod D fixed to the stage plate. Likewise on the stage plate is the support for the tube E. The rough adjustment of the microscope can be made by a rack and pinion P, and the fine adjustment by the screw G. The tube containing the eyepiece and the objective is double. The inner tube H is movable, making a change in the length of the tube possible. As a rule this inner tube has a mark which allows the length of the tube to be set.

It is most important the stand should be free of vibration. A fine adjustment is also necessary, in order to perform conveniently and with certainty the slight motion of the microscope in relation to the object. In the microscope the fine adjustment was worked by moving the inner tube by hand, but the more convenient rack and pinion is now used almost exclusively.

For slight magnifications rough adjustment is sufficient, but with objects of the order of a micrometer, a fine adjustment is wanted. Very different constructions are in use. Almost all are such that the whole microscope tube is raised or sunk by the mechanism of the fine adjustment, and not only the objective. The most used is the micrometer screw adjustment (fig. 51). The tube carrier B fits closely on to a column A which is fixed firmly to the stage plate. The end of the column C is traversed by the micrometer screw II which is set in action by the knob E. The column A contains a powerful spiral spring, which exerts a strong pressure on the plate F fixed to the carrier B. By screwing in the micrometer, the spring is compressed and the tube lowered. By the contrary movement the spring pressure raises the tube as far as is allowed by the screw. The strong pressure of the spring practically excludes motion, which with fine adjustments is very important. Another very good adjustment is that of Messrs. Swift & Son, shown in fig. 52. The long lever D is pressed to one side by the screw F, and is thus turned round the pin E. On the tube very near to the pin E is a cylinder C, which by the action of the screw F is very slightly raised or lowered. A double lever is used in a fine adjustment by Messrs. Watson & Son (fig. 53). According to whether the screw A or B is used, the adjustment is fine or coarse. In other fine adjustments by means of springs and balance wheels either a micrometer screw is moved (Zeiss), or a curved disk fixed to the balance wheel is turned (Leitz), or an oblique disk arranged more or less in a circle and attached to the balance wheel is revolved (Reichert). These modern adjustments are made so exact that motions can be easily measured.

up to 0.002 mm. An essential in all rough and fine adjustments is that the motion must always be parallel to the optical axis of the microscope, so that the same point in the object remains in the field of view.

Another condition which must be fulfilled by a good stand is the power of inclination. It is only rarely necessary to bring the preparation ready horizontally; and for easy observation, especially when it will take a long time, it is of great assistance to be able to turn the microscope exactly. The microscope can be inclined, so that the observations can be made in a natural position. The apparatus is arranged so that the microscope can be placed in all positions between the vertical and the horizontal. The position is sometimes necessary if photographs are to be taken by the microscope.

Many devices are available for changing the objective. It is essential that the objective is always brought down to the lower magnification in such a way that the plate (fig. 60, Plate). The revolvers may hold two, three or four objectives. In the sliding changer the objective is, dovetailed to a slide, the correct position being secured by clamps. Fully equipped microscopes have apparatus for moving and turning the object. In simple microscopes the stage plate lies on the stand held by two springs, and must be moved by the hand (fig. 60, Plate). For elaborate work a so-called cross-table is indispensable. By means of screws the stage plate is movable in two directions at right angles to one another, in the plane of the stand. In some cases the stand is also movable round the optic axis.

The microscope stands described above can be used for the greater number of the naturalists' experiments. If the thickness of the crystal is known, or the thickness of the crystal when the index is known, a fine adjustment A makes it possible to measure exactly the changes in the length of the microscope. Further, a revolving stage stand provided with a graduated scale B is used to determine the angle in crystals. To obviate mistakes the optical axis of the microscope must coincide with the revolving axis of the plate, and the revolving plate has a central position C to keep this condition fulfilled. The stands the objective can be centred instead of the plate. For measuring this angle, an eyepiece with cross-threads is used. In the lower focal plane of the eyepiece, at the spot where the real image which the objective forms on the object, a glass plate is introduced which has two fine cross lines or even two very thin threads. The eye-lens can be adjusted for the thread-plate, so that different observers can see the cross clearly. The cross is always adjusted first. When observing with such an eyepiece, care must be taken that the real image of the object lies in the plane of the cross threads, i.e. that there is no parallax. The adjustment is easily controlled. If the eye is moved to and fro over the eyepiece and the image makes apparently similar movements in rotation to the cross threads, the image does not yet lie in the plane of the cross threads.

To measure the angle, the images of the crystal edges are covered in turn by one of the threads by turning the table, and the angle of rotation is read from the scale. A cross-table is very convenient for this calculation, for with the aid of the two movable slips situated in the plane of the plate at right angles to one another, the point where the two crystal edges intersect can be quickly and correctly brought into the revolving axis of the plate. This measurement can also be made with a goniometer or quadrant, in which case the double-marks are used instead of the cross threads. The fitting of the eyepiece at the upper end of the tube is provided with a graduated circle. The eyepiece proper is with the parallel strokes can be revolved, and the rotation be read from the graduated circle at right angles to the plane of polarization. Based on this calculation the marks of the thread-plate have only to be placed exactly parallel to the crystal edge.

For examining preparations in polarized light a polarizer D is introduced in the illuminating apparatus at the upper side of the eyepiece E above the eyepiece. The analyzer can be rotated, the angle being read by a divided circle F. Very often the analyzer is placed in the tube, a little above the objective: it is then generally in a case G, which can be put into the tube. The placing of the analyzer near the objective has the advantage that the field of view is not restricted, as is the case if the analyser is used above the eyepiece. Nicol's, Glan-Thomson prisms or similar polarizing apparatus are used as polarizers and analyzers. Below the analyser G a plate H of selenite or mica may be put in the course of the rays. This small plate can also be laid above the polarizer in the illuminating apparatus or in the eyepiece.

To examine crystals, especially in convergent light, a condenser, movable in the optic axis, is needed above the polarizer. The image produced by the microscope objective M in its back focal plane is then observed through a supplementary microscope. The objective of this supplementary microscope, the Bertrand lens, can be applied through a window I at the lower end of the inner tube K. By using a rack and pinion movement L the supplementary microscope can be adjusted for the images. There is nearly always an arrangement to observe the preparation first in convergent light and then in parallel polarized light. This change can often be brought about by taking away or adding parts of the condenser.

**MICROMETRY**

It is often required in micrometrical work to determine the size of objects or parts of objects.

There are three essential ways of performing this. The first method uses the objective screw micrometer. The object is placed on a slide in the plane of the stage plate and able to be very finely moved by the micrometer screw, which has as fine a worm as possible. A divided cylinder is fixed to the turning knob, which thus makes it possible to measure fractions of the revolution. The revolutions of the cylinder are registered by a calculator. The use of an eyepiece with a cross thread is essential to this measurement. After the microscope has been so adjusted that the image of the object to be measured falls exactly in the plane of the cross threads, the object is moved by the micrometer until one edge of the object is exactly covered by a thread. The micrometer is now read. Then the object is moved by the micrometer till the image of the other edge is covered by the thread in the eyepiece, and the micrometer is again read. The difference between the two positions gives the size of the object.

The objective screw micrometer is, however, not sufficiently delicate, and is only used when comparatively large objects are to be measured, and especially for objects whose edges do not appear at the same time in a slide of viewed objects. The micrometer is then moved till another graduation corresponds to the other edge of the image the size of the image can be read off. As this method measures

---

**FIG. 53.**—Double Lever Adjustment of Watson & Sons.

**FIG. 54.**—Screw Micrometer Ocular. Sectional elevation and plan (Zeiss).
the image correctly to a few thousandths of millimetres, the object itself is measured accurately to some hundred-thousandths of millimetres, if it has been magnified a hundred times by the objective.

To keep up this degree of exactitude the magnification of the objective must be carefully ascertained, e.g. by using an objective meter. A fine scale with known intervals is put on the stage plate, and by determining the distance between the graduations of the objective micrometer formed through the same objective, by means of the screw micrometer ocular, the magnification of the objective is determined. As the errors in the graduation of the objective micrometer are also magnified, very exact scales are necessary. When determining the magnification the microscope must be used under exactly the same conditions: neither the length of the tube nor of the object is to be altered.

A fixed eyepiece micrometer is simpler and more popular. This consists of a scale on a little glass plate, which, instead of a cross wire, is placed in the eyepiece. The adjustment must be such that the image produced by the eyepiece is equal to the image produced by the eyepiece scale.

The size of the image is determined by calculating the entire interval taken up by it. By using an objective micrometer in place of the object, the magnification of the objective can be ascertained and from this the actual size of the object. As fractions of the interval can only be estimated in this method, a measurement with such an eyepiece scale can of course not be as exact as with a screw micrometer ocular. However, such a determination of size is often quite accurate enough.

A third method employs a drawing prism. The object and the drawing plane are seen at the same time and the outlines can be readily drawn. If, as before, an objective micrometer is placed below the microscopically observed object, and the size of a special micrometer-interval is drawn on the same board, then the actual size of the object can be ascertained. Instead of first drawing the object and the objective micrometer, they can of course be projected at the same time on a drawing plane.

The errors attending the determination of the size of a microscopic object depend chiefly on the accuracy of the objective micrometer; any errors in the eyepiece being magnified by the objective. These may be diminished by using different intervals of the objective micrometer, and comparing the eyepiece scale, and the calculation of the scale is based on the found mean value. A second error can arise through the inaccuracy of the eyepiece micrometer, and also in the case of a screw micrometer through periodic faults of the screw, and there is some doubt as to the correctness of the measurements. This allows its errors to be diminished, if one measures at different points and then fixes a mean value.

The dead motion of a micrometer screw is best avoided by working the screw always from one and the same side. The machine may also occasionally a fault. For this reason there is sometimes employed two very narrow threads lying beside one another, and which limit the image as nearly as possible.

THE TESTING OF THE MICROSCOPE

The excellence of a microscope objective depends on its definition and its resolving power.

The definition is better according as the chromatic and spherical aberrations are removed; there always remains, however, in even the best constructions some slight aberration. In consequence of these residual aberrations, e.g., 55, is obtained by means of a stop an ideal image-point, but as a small circle of aberration. These circles will be objectionable when the smallest details are examined. The size of these circles depends, as already indicated, on the diameter of equal tube lengths, only on the type of the objective, and not on the focal length, exact execution being assumed. Object details will only be clear up to the edge of the circle, and in general the limit of the length of the objective be brought to the right value. In the case of a suitable ocular magnification, the details will be seen, as long as the circle is not cut by the edge. This limit of the circle may be small in comparison. The size of these details in the image depends only on the magnification of the objective, \( M = \Delta f/f_s \), and can be obtained by subtracting from the length of the objective the length brought to the right value. In the case of a suitable ocular magnification, the details will be seen, as long as the circle is not cut by the edge. This limit of the circle may be small in comparison. The size of these details in the image depends only on the magnification of the objective, \( M = \Delta f/f_s \), and can be obtained by subtracting from the length of the objective the length of the circle, which is obtained by the formula:

\[
\text{circle} = \left( \frac{f_s}{\Delta f} \right) \cdot \text{diameter}
\]

This is therefore possible to judge the excellence of the focusing of objectives on the strength of the ocular-magnification, or the over-magnification, which they permit, and by comparing the size of circle, which is obtained by the so-called delicate ray transmission, suggested a way by which the quality of the images of objectives can be observed. The ray transmission, shown by the formula:

\[
\text{transmission} = \frac{1}{M^2} = \frac{f^2}{f^2}
\]

of the iris diaphragm, on two separate fields, which magnifies contain rays of the iris diaphragm, and then the image of the magnified diaphragm is projected on a screen. By comparing the size of circle, which is obtained by the so-called delicate ray transmission, suggested a way by which the quality of the images of objectives can be observed. The ray transmission, shown by the formula:

\[
\text{transmission} = \frac{1}{M^2} = \frac{f^2}{f^2}
\]

of the iris diaphragm, on two separate fields, which magnifies contain rays of the iris diaphragm, and then the image of the magnified diaphragm is projected on a screen.

The entrance pupil is in this way reduced to a point, and hence the smallest rays of light can only be seen when the tube has been cut. This should, of course, be done only when the image is not disturbed.
There are many methods for determining the focal length of the objective. The objective to be examined is placed on the stage, and in the manner just shown, the distance of the focal plane from the edge of the fittings or to the surface plane of the front lens is determined. Any plane object a few yards distant can be used. If the object can be seen by using the mirror, the plane mirror must be used; then the actual size of the object and of the image produced by the objective is measured (of the image by a micrometer ocular). The length of the focal plane of the objective is next determined. This distance is composed of the distance of the objective from the centre of the planar mirror, and of the distance of the focus on the stage plane from the centre of the plane mirror. Let the size of the object by \( y \), the size of the image \( y' \) the distance of the object from the focus \( x \), then \( y/y' = x/f_1 \) from which \( f_1 \) can be calculated (see LENS). The same method can be used to determine the focal length of the eyepiece. These are the dimensions necessary for determining the magnification of the microscope. Knowing the optical length of the tube \( \Delta_1 \), the focal lengths of the objective \( f_1 \), and of the eyepiece, \( f_2 \).

The focal length of an objective can be more simply determined by placing an objective micrometer on the stage and reproducing on a screen some yards away by the objective which is to be measured. If the size of the image of a known interval of the objective micrometer is determined by an ordinary scale, and the distance of the image from the focal plane of the objective belonging to it is measured, then the focal length can be calculated from the ratio \( y/y' = x/f_1 \), in which \( y \) is the size of the object, \( y' \) that of the image, and \( x \) the distance of the image from the focal plane belonging to it.

Besides this indirect method of determining the magnification there is another, which is necessary to give accurate results, it is more convenient and simpler than the indirect method.

Mikroskopie (Gr. \( τύφος \); \( τύφω\), to cut), the terms relating to the preparation of minute sections of organic tissue for the microscope. In 1875 the methods were yet in their infancy; their development has enabled observers to achieve the most exact study of minute anatomy, in the case of small objects, which without these methods could only be investigated by the unsatisfactory process of focusing with the microscope through the solid object.

It is not necessary here to detail at length the wet method of preparing sections. Briefly, the tissue is soaked in a solution of gum, or of gum and syrup, and after being frozen by ether spray, or by a mixture of ice and salt, is cut into sections either by the Rutherford, Cathcart or some similar section-cutter, or by apparatus which can be fitted to the more modern types of microtome referred to below. This method, which is to-day used mainly by pathologists, has two main disadvantages: the prolonged action of watery fluids on the tissues, and the impossibility of getting ribbons, each section having to be picked up separately.

The general processes of the dry method employed in zoological and botanical microscopy are, up to a certain point, practically identified with those used for the preservation of animals and their tissues for other branches of microscopic work. In the first place the tissues must be killed; in the second, they must be fixed, i.e. the protoplasm must be set or coagulated as far as possible in the condition in which it appears in life; and in the third, they must be hardened, i.e. in most cases dehydrated. Killing may be effected by asphyxiation or narcotization (nicotine, cocaine, chloral hydrate, &c.) in special cases, but is generally achieved by fixing reagents, of which corrosive sublimate and other chlorides, picric, acetic, osmic and chromic acids, alone or in combination, chromates and strong alcohol are the most usual. These serve to a great extent also as hardening agents, but alcohol, used after them, completes this process effectively, and when not too strong (70%) is the best storage fluid. The second set of processes relates to the staining, without which transparent sections are almost invisible.

The stains are divisible into general stains, which dye the tissues practically uniformly and indifferently; and selective stains, which have affinity for special tissues or cell elements. Of the latter group some fasten on nuclei, others on the chromatia of the nuclei; some on connective tissues, others on muscle fibres and so on. It is probable that the action of all these selective stains is produced by definite chemical combination with compounds originally present in, generated in, or introduced into the tissue selected. The most generally useful stains for ordinary work belong either to the cochineal series (borax-carmin, Carmalum, &c.), or to the logwood series (haematoxylin, haemalum, iron haematoxylin, &c.); in both of these the general improvements have been introduced of late years by Dr Paul Mayer. The activity of these stains apparently depends upon the presence of alumina or of some similar base. For most special researches, such as cytology, neuropathology, neurobiology, &c., so far as the staining of the tissues is concerned, it is more usual to use the coal-tar colours, the name of which is legten. Some of these, such as safranine or gentian violet, are regressive stains; that is to say, the tissues are overstained uniformly, and the superfluously colouring matter washed out either by alcohol or by weak hydrochloric acid from the unselected parts. Others, such as methyl green, are progressive—that is, the colour is brought up to the pitch required and the reaction promptly stopped. The coal-tar stains can be used singly, or in combinations of two or three. Some of the best, unfortunately, are not permanent. A third group of stains is furnished by such reagents as silver nitrate, gold chloride, and the like (impregnation stains), which can be made not only to stain, but also to deposit a fine metallic precipitate on certain structures. In the case of small and delicate objects, the staining is done in the mass before any further preparation for sections, but with larger animals, or large pieces of resistant tissue, the stain is applied to the sections only. The processes so far mentioned are applicable to many branches of microscopic work.

When preparing tissues for sections the first step is complete dehydration, generally effected by bringing the object into absolute alcohol. It is then transferred to one of a group of reagents, which are miscible with absolute alcohol, but would form an emulsion with water, and are solvents of the embedding medium. The embedding mass in most general use is paraffin wax, melting at a temperature of 54° to 60° C., according to the character of the object and the thickness of section required. The object is transferred from absolute alcohol to benzol, chloroform, cedar oil, or similar fluid to the melted paraffin; the fluid diffuses and evaporates, leaving the tissues to be completely permeated by the paraffin. This process can be greatly hastened by the use of a partial vacuum. When impregnation is complete the paraffin is cooled rapidly, so as to assume a homogeneous non-crystalline condition, and the tissue thus comes to form part of a block of soft but tenacious material, which protects it from damage by air or damp, and can be readily cut by a knife. The block is then trimmed to the form of a triangle or rectangle, and fixed by a clump or by local melting in the holder of the microtome.

The first automatic microtome suitable for cutting a block of tissue into a continuous series of sections was made in 1883 in the university workshops of Cambridge, from a design by W. H. Caldwell and R. Threlfall. Only a single machine was made, but in 1884 twelve machines were made by the Cambridge Scientific Instrument Company from a design by Caldwell. Since then numerous excellent and simpler forms of microtome have been evolved. Some of these have distinct advantages over others, but with microtomes as with other tools—the success of the results depends very largely on the manipulator, for every one works best with his accustomed instrument. In one type of microtome the razor is attached at one end only to a heavy
block, sliding backwards and forwards in a horizontal V-groove; the paraffin block is fed to this either up a vertical guide (Schanze, Reichert, &c.) or up an inclined plane (Thoma-Jung). In another type the razor is firmly clamped at both ends, to diminish vibration, and the paraffin block advances to it at the end of a long lever on trunion bearings (Cambridge rocker) or up a vertical guide (Minot types).

In the selection of a microtome, apart from its steadiness, rigidity, accuracy of workmanship, and so forth, it must be borne in mind that, in general, simplicity of working parts means longer life, and that an elaborate "automatic" mechanism, by which a single movement is translated into several in different directions, not only complicates the machine, but robs the operator of those alterations of pace, rigidity, pressure, &c., which are often necessitated by the varying texture in different parts of the object cut. For general use by less skilful students in a laboratory, price, simplicity and rapidity of work recommend the rocking microtome of the Cambridge Scientific Instrument Company, but it tends to fail at large or hard objects. For the all-round work of an investigator, its simplicity and finish have made Jung's sliding microtome with the Naples improvements deservedly popular for many years; it can be fitted with special apparatus for cutting celloidin and frozen objects, and it can be relied upon to cut any tissue, however difficult; but it cannot be worked as rapidly as some others, nor produce long ribbons of large objects. For this latter purpose the Minot-Becker, Minot-Zimmermann and Reinhold-Gilltay have been strongly recommended; these, however, are all of more complicated construction, with corresponding liability to uneven wear and damage; they are highly "automatic", leaving nothing but pace under control of the operator, and they are (particularly the last) expensive.

In 1910 the Cambridge Scientific Instrument Company issued a new microtome designed primarily for cutting larger sections than was possible in their earlier forms, which respectively dealt with sections 12×20 mm. and 30 mm. in diameter; the new instrument cuts sections measuring 150×120 mm. (6×5 in.), embedded in paraffin or celloidin and of a thickness varying from 0.002 to 0.06 mm., each division of the scale being equal to 0.002 mm. and the total distance of automatic feed being 21 mm. The construction and action of the instrument can be understood by referring to the figure; a detailed description is given, since the same principles are utilized to a greater or less extent in all sliding microtomes.

Large Sliding Microtome.

The object to be cut, having been embedded in a suitable preparation A, is fixed to a wooden block which is attached by clamps to the object-holder B. The object-holder is provided with mechanism by means of which the height of the block is determined; this is effected by mounting the holder in a cup-shaped socket at the extremity of a brass pillar E, which can be raised or lowered and fixed in any position by a clamp. In addition, the direction in which a section is cut can be varied by adjusting the four screws, one of which is shown at C, which orientate the block. The object-holder and feeding mechanism are carried on a sliding carriage which rests at three points on two guides in the frame N, N of the instrument; and in order to secure easy running the necessary lubrication is provided by a reservoir on which oil is placed. The motion of the carriage in either direction is effected by the handle G, connected to a system of levers H, which, being constructed on geometrical principles, prevent any side-play in the carriage and ensure a uniform motion. A means of determining the thickness of the section cut consists of a stop-pin, which, operating through the ratchet M, causes a toothed wheel to revolve, which in turn raises the pillar K; the amount of the motion can be read off by an index. On the return stroke of the sliding carriage the stop-pin is again situated in such a manner that just before the knife R reaches the object-holder the mechanism depresses this part of the instrument so that the knife is not fouled; and after its passage the object-holder is raised to the starting position. The knife R is rigidly set in two heavy brass clamps adjustable by the screws S, and these clamps are attached to the frame of the instrument by the screws T. The angle which the cutting edge makes with the frame is also adjustable, and by means of a mall angular scale engraved on the knife-holders any setting can be easily determined or repeated. The knife is flat on one side and hollow-ground on the other. In using the microtome it is essential that the cutting edge of the knife points towards the end of the instrument where the handle is placed; the hollow-ground face should be uppermost, and the flat surface should not be exactly horizontal but slightly inclined so that the lower facet of the cutting edge is parallel to the frame. It is also necessary to be sure that in the direction of motion, it is the usual practice, when paraffin sections are to be taken, to have the cutting edge at right angles to the motion; when, on the other hand, celloidin preparations are being cut, the knife is held obliquely in the direction of motion. The arrangement is very convenient. This oblique setting is also recommended for paraffin sections. In addition it must be remembered that celloidin preparations always require lubricating when being cut, and it is also necessary to keep both the knife and the preparation constantly moistened with either 80% alcohol or with cedar-wood oil.

The sections, when cut by the microtome with the knife straight and the two sides of the rectangular paraffin block parallel to it, in most cases can be got off in a continuous ribbon, each sticking to its predecessor. This very desirable result generally can be insured by a coating of softer paraffin; but if the object be large, or brittle, or of varying texture, it is safer to cut the sections singly from a triangular block with an oblique knife. The sections or ribbon are often not quite flat, but rolled, creased or compressed; they must be flattened before being attached to the slide. It is possible to carry out these two processes simultaneously by covering the carefully cleaned slide with plenty of a very dilute solution of Mayer's glycerine and albumen, and laying the sections on the fluid and the slide on a hot-plate; as the water becomes warm the sections flatten out, and as it evaporates they settle down on the slide, and are held there by the albumen (many other methods are in use). The slide is then warmed to melt the paraffin, and replaced on to a similar fluid which removes the paraffin/thine into absolute alcohol, which dehydrates and coagulates the albumen. If the tissue has not been stained en bloc the sections can now be stained on the slide. After staining they are fully dehydrated, rendered transparent by oil of cloves, and mounted in xylol-dammar or Canada balsam. W. Giesbrecht was the first to fix sections on the slide, using a solution of shellac in creosote in 1881; and also in the same year and in the laboratory of the Naples aquarium, W. H. Caldwell first cut and fixed ribbons of sections.

For ordinary work the paraffin method excels all others for rapidity, certainty and cleanliness; but for large and hard objects, or crumbling tissues (such as ova with a large quantity of yolk), some manipulators prefer to embed in celloidin. By this method, after dehydration, the tissue is soaked in a mixture of absolute alcohol and xylol, or benzol. The tissue is then transferred either to increasingly strong solutions of celloidin in the same mixture or to a thin solution which is then boiled down till stiff. The celloidin mass is then hardened: at first, if necessary, by drying; afterwards by a bath of chloroform or its vapour. It can then be cut in the microtome, either wet, or
previously cleaned with cedar oil) dry like a paraffin block. The method is more tedious and more messy than the paraffin process; but amongst its advantages must be reckoned that little or no heat is required, and that the embedding mass is transparent, though it does not allow of such thin sections as paraffin.

The above accounts present an outline of the complex processes employed to-day, by which, on the one hand, sections 30 µ in thickness may be made through the entire human brain; and, on the other, organisms invisible to the naked eye may be cut into a long ribbon of consecutive sections 1 µ (one-thousandth of a millimetre) thick, every minutest fragment being retained in its proper place.

The standard book on the subject is Bollée Lee’s Microtome’s Guide–manual. Other works are G. Mann, Methods and Theory of Microtome Section (Oxford, 1907); and A. Flatter, Microtome and Microscopical Physiological Research (London, 1905). (G. H. F.)

MIDAS, the name of several Phrygian kings. The first of these was said to have been the son of Gordius and Cybele, whose first priest he was, and in whose honour he founded a temple at Pessinus. Having taken the drunken Silenus back to his youthful charge Dionysus, he was rewarded by the god with the power of transforming everything he touched into gold. Finding himself in danger of starvation, even his food and drink being changed by his touch, Midas entreated Dionysus to take back the gift. By the command of the god he bathed in the river Pactolus, which henceforth became auriferous (Ovid, Metamorph. xiv. 874 5; H. P. Fall, A Romance of 1902, p. 16). Midas, with the musical contest between Apollo and Marsyas (or Pan), Having decided against the god, his ears were changed into those of an ass. He concealed them under a Phrygian cap; but the secret was discovered by his barber, who, being unable to keep it, dug a hole in the ground and whispered into it “Midas has the ears of an ass.” He then filled up the hole, thinking his secret safe; but the reeds which grew up over the spot proclaimed it to all the world. Midas with the ass’s ears was a frequent subject of the Attic satyr-drama. There is no doubt that Midas was the name of one or more real persons among whom legendary legends have grown up. The name “Midas the king” occurs on a very ancient tomb in the valley of the Sangarius, the legendary seat of the Phrygian kingdom. The Phrygian monarchy was destroyed by the Cimmerians about 670 B.C., and the name Midas became in Greek tradition the representative of this ancient dynasty.

MIDDELBURG, the ancient capital of the province of Zeeland, Holland, in the middle of the island of Walcheren, 4 m. by rail N. by E. of Flushing, with which it is also connected by steam tramway and by ship canal (1873), which continues to Veere on the N.E. coast, with a branch eastward to Arnemuiden. Pop. (1903), 19,002. Middelburg contains many splendid old houses, which recall the prosperity which distinguished it until the end of the 18th century. The beautiful town-hall, built by Anton Keldermans about 1512, with a square tower 180 ft. high, and a façade adorned with statues of the counts and countesses of Zeeland and Holland, contains the valuable city archives and antiquarian and historiographical collections. The old abbey of St Nicholas, founded in 1130, and now occupied by the provincial council, has some fine old tapestry of the end of the 16th century. The building was added to in the 14th and 15th centuries, and partly rebuilt after a fire in 1402. It was the scene in 1505 of a meeting of the knights of the Golden Fleece, and was frequently the residence of royal visitors, including Maximilian, Philip the Fair and Charles V. The abbot of Middelburg formerly possessed a vote of his own in the Provincial States. What was formerly the nave of the abbey church is now the New Church, and the ancient choir constitutes the Choir Church. These churches are interesting for the monuments of William II., count of Holland, king of the Romans (d. 1256), the 16th century scholar Hadrian Junius, and Jan Pieterszoon; and the tombs of Jan and Cornelius Evertsen, who fell in the naval war against England in 1666. The high tower (280 ft.), known as de lange Jan, standing apart from the church contains a good chime of bells. The corn exchange, the hof St Joris and the hof St Sebastian (formerly buildings belonging to the gilds of anchormen, and now places of amusement) also deserve mention. The museum of antiquities belonging to the Zeeland Society of Arts and Sciences (founded at Flushing in 1769, and transferred to Middelburg in 1801) contains a complete collection of the fauna and flora of the province, many maps, plans and drawings relating to Zeeland, the first telescope made by Hans Lippershey and Zacharias Jansen in Middelburg in 1608, and some provincial Roman antiquities.

The extensive trade which Middelburg formerly carried on with the East and West Indies and with England and Flanders, was ruined by the war with England and the French occupation. But the construction of the railway in 1872, followed by the opening of the ship canal and the large dock (1875), as well as the establishment, by the aid of the chamber of commerce, of certain manufacturing industries (iron, machinery, furniture, oil and cigars), lifted it out of its isolation.

MIDDELBURG, a town of the Transvaal, 98 m. E. by rail of Pretoria, and 251 m. W. of Lourenço Marques. Pop. (1904), 9085—of whom 2343 were whites. It is prettily situated on the banks of the Olifants River. Middelburg is an administrative division of the same name, and is a trading centre for a large district. It is also the centre of one of the richest coalfields in South Africa. From some of the adjacent collieries excellent steam coal is obtained. Copper and cobalt are found in the neighbourhood.

Middelburg was chosen in 1901 as the place of conference for peace negotiations between the British and the Boers. After the occupation of Pretoria in June 1900 by Lord Roberts the Boer forces had been reduced to guerilla warfare, and Lord Kitchener, learning that the Transvaal commandants were despondent, invited General Botha to enter into negotiations, on the basis of the recognition of British sovereignty. The conference between Lord Kitchener and General Botha was opened on the 28th of February and the negotiations, which ended in failure, were protracted until the 16th of March (see Transvaal: History, § The War of 1899–1902).

Middelburg is also the name of a town in the Cape Province, South Africa, 550 m. N. by W. of Port Elizabeth. Pop. (1904), 6937.

MIDDLE AGES, THE. This name is commonly given to a period of European history which lies between what is usually known as ancient and modern times, and which has generally been considered as extending from about the middle of the 5th to about the middle of the 15th centuries. The two dates adopted in old textbooks were 476 and 1453, from the setting aside of the last emperor in the West until the fall of Constantinople. In reality it is impossible to assign any exact dates for the opening and close of such a period. The trend of recent historical research leads one even to doubt the validity of the very conception of any definite medieval period. The evolution of modern European society has been continuous. Progress has not been uniform. There was much retrogression with the intrusion of new barbarian races; but from their absorption by the 7th century until the 20th there is not a century in which some notable gain was not made towards the attainments of modern civilization. The correct perspective between the summits of modern and ancient times, not a long level stretch of a thousand years, with mankind stationary, spell-bound under the authority of the Church, absorbed in war or monastic dreams, but a downward and then a long upward slope, on both of which the forces which make for civilization may be seen at work.

It is clear that a survey of the history of these so-called middle ages—long use makes the term inevitable—must include not only the political phase, but also economics, religion, law, science, literature, &c., since all are involved in the concept. A hurried outline of each of these vital branches of our civilization will at once reveal the falseness of the usual periodizing. It is only after having traced these one by one that we can properly review the process as a whole.
In political history, the epochal fact which marks the close of ancient times is the decline of the Roman Empire. This was a process extending over three or four centuries, in which no one date lends itself to the historian. The deposition of Romulus Augustus, the last Roman emperor in the West, in 476, was certainly not one of those events upon which the history of the Western world depends. Outwardly it did not mark the end of the Empire, but the restoration of imperial unity. The throne in Italy had been vacant before, and the restoration of unity was realized in fact under Justinian. There is no reason why the date 476 should stand out in European history more strongly than half a dozen other such dates. Yet we may say that the 5th century did witness the actual dismemberment of the Roman Empire. The new nations in Spain, Gaul, parts of Italy and Britain were forming the rude beginnings of what were to become national states in the centuries following. Western Europe was taken out of the imperial mould and broken up. This is a revolution of sufficient magnitude to be regarded as politically the opening of a new era. It had been long preparing in the economic and administrative decline of the Empire, and in the steady influx of Germanic peoples into Roman territory for over two centuries; but the power of the old civilization to absorb the new races was exhausted by the 5th century, and the political history became dominated by institutions. That path, however, was not destined to end blindly in a "middle age." The line of political development marked out in the 5th century—that of the national state—still continues. The revolution in which Alaric, Theodoric and Clovis figured did not set the problem for the middle ages only, as is frequently stated; its full meaning did not appear until the Peninsula War, the Prussia of Stein and Scharnhorst, and even Solferino and Sedan. Thus the 5th century politically introduces not so much the history of the middle ages as that of modern Europe.

The immediate introduction, however, was a long one—so long and so distinct from the later development as to constitute in itself a distinct phase. For five or six centuries—from the 5th until about the 11th—comparatively little permanent progress was made. The Germanic tribes were still adjusting themselves and slowly learning to combine their primitive institutions with the remains of those of Rome; the premature union under Charlemagne gave way before new invasions, and anarchy became crystallized in feudalism. It was not until the 12th and 13th centuries that modern national states really took shape: England with its trial by jury, civil courts, Magna Charta. That path, however, was not destined to end blindly in a "middle age." The line of political development marked out in the 5th century—that of the national state—still continues. The revolution in which Alaric, Theodoric and Clovis figured did not set the problem for the middle ages only, as is frequently stated; its full meaning did not appear until the Peninsula War, the Prussia of Stein and Scharnhorst, and even Solferino and Sedan. 15th centuries, is so easily marked off and played so considerable a rôle in the academic history of that time, that historians often refer to it as the only intellectual interest of "medieval" men. Then, selecting some of the later and less virile scholastics as victims, they ask how men could be seriously interested in their trivialities. But these men were not all busy over the problem of how many angels could stand on a needle-point; nor were they all dominated by the religious spirit of faith or intellectual cowardice. They were searching for truth with scientific eagerness. Their very failure made possible the modern era. It is perhaps unnecessary to point out how small a proportion of the "intellectuals" were scholastics even in the 13th century.

In the realm of art the "middle ages" had already set in before Constantine robbed the arch of Titus to decorate his own, and before these museums of antiquity, the temples, were plundered by Christian mobs. The victory of Christianity—iconoclastic in its primitive spirit—was but a single chapter in the story of decline. The process was completed by the misery of the decaying empire, and by the Germanic invasions. The barbarians, however, destroyed less than has been commonly supposed. Destruction was more the product of necessity than of wantonness. Thus public monuments became fortresses, and antique sculpture was built into city walls. Such art as continued was almost wholly religious; for in the wilderness of the times the churches formed oases of comparative prosperity and peace, and, even in the darkest times, wherever such oases existed there the seeds of art took root. The Church architecture of the "middle ages," then developed naturally and without a break, through the Byzantine and Romanesque styles, out of the secular and religious architecture of Greece and Rome. And, with the return of comparatively settled and prosperous conditions, not only architecture but the other arts also blossomed under the influence of what was later stigmatized as the "Gothic" spirit into new and original forms. Down to the Reformation the churches continued to be, as the temples of the ancient world had been, the main centres of the arts; yet the arts were not confined to them, but flourished wherever, as in castles or walled cities, the conditions essential to their development existed. With the revival of civilized conditions in secular life, secular ideals in art also revived; the ecclesiastical traditions in painting and sculpture, which always tend to become stereotyped, began in the West to be encroached upon long before the period of the "Renaissance." The 12th and 13th centuries, which witnessed the great struggle between the secular and spiritual powers in the state, witnessed also the rise of a literature inspired by the lay spirit, and of an art which was already escaping from the thrall of the stereotyped ecclesiastical forms. Gothic sculpture was not independently decorative, it was an essential element in the harmony of the architectural design. The elongated kings that guard the door of Chartres Cathedral, or the portals with the Last Judgment, are a necessary element in the façade. Thus fettered, even the realism of the Gothic sculptors failed, except in rare instances, of its full implication. The Gothic arts of the West, the arts of France, Italy, and Bohemia, models were at hand, and the glory of its achievement in the 15th and 16th centuries was so great as to obscure in men's eyes what had been done before.

But this Italian renaissance was not the only one. It was but one of many; and it was concerned with the two subjects which perhaps least deeply influence the lives of the mass of men—literary humanism and art. It is obviously absurd, in the face of the foregoing facts, to regard it as the end of a middle age in anything but in its own field.

When one studies the history of Europe subject by subject, as indicated above, and not merely in a monastic chronicle of things in general, chosen according to the author's point of view, one sees the old-time framework passing away. The traditional idea of a barren middle age and a single glorious renaissance proves false. An organic study of the past reveals a more rational picture of the process which produced the Europe of to-day. Cataclysm and special creation here as elsewhere give way to evolution. The new synthesis reveals a universal decline from the 5th to the 10th centuries, while the Germanic races were learning the rudiments of culture, a decline that was deepened by each succeeding wave of migration, each tribal war of Franks or Saxons, and reached its climax in the disorders of the 9th and 10th centuries when the half-formed civilization of Christendom was forced to face the migration of the Northmen by sea, the raids of the Saracen upon the south and the onslaught of Hungarians and Slavs upon the east. That was the dark age. It left Europe bristling with feudal castles, and already alert for the march of progress. At once the march begins. Henry the Fowler beats back the Slavs and places the outposts of Christendom along the Elbe and the Oder. Otto I., his son, drives the Magyars from southern Germany and establishes the East Mark (Austria) to guard the upper Danube. The restoration of the Empire in 962 marks the first milestone on the pathway of recovery. Already scholarship had found a home in monasteries planted in the heart of the German forests. The succeeding century brought the Empire to the acme of its power, until Henry III. in the Synod of Sutri, sat in judgment on the impotent and demoralized papacy. Meanwhile France had been learning something even in its feudal anarchy. The monks of Cluny were at work. The Capetians had begun. The great monastery of Bec was drawing the sons of northern sea-robbers to the service of that greatest civilizing force, the Church. The progress made through even this darkest age may be measured by the difference between the army of Rollo and that which William the Conqueror gathered for the invasion of England.

There is a legend, current among historians from the days of Robertson and Hallam, that as the year 1000 approached mankind prepared for the Last Judgment; that the earth "clothed itself with the white mantle of churches," and like a penitent watched in terror and in prayer for the fatal dawn. Contemporary sources fail to bear out this beautiful conception. Apart from the fact that reckoning from the birth of Christ was by no means universal, and consequently the mass of men were ignorant that there was such a thing as the year 1000, one wonders how that most enduring type of architecture, the Romanesque, had reached its maturity among men who thought that the earth itself was so soon to "shrive like a parched scroll." Recent scholarship has absolutely disproved this legend, founded on a few trite phrases in monastic chronicles, and still to be heard in similar contexts. The year 1000 marks no epoch in medieval history.

The latter half of the 11th century witnessed the most remarkable political creation in Europe since the days of Caesar, the papal monarchy of Hildebrand. The great scholastic controversies had already begun in the schools of France; the revival of Roman law had called forth the university of Bologna, and the canonists had begun the codification of the law of the Church. The way was already cleared for the busy 12th century—the age of Louis VI. and Henry II., of Glanvill and Suger, of Abelard and Maimonides, of Frederick Barbarossa and Alexander III., of the emancipation of French communes and cities and the independence of the townsmen, and the extension of commerce, of trouvère and troubadour and the beginnings of vernacular literature of the creation of the Gothic art, of trial by jury and the supremacy of royal justice. Such are but a fraction of its achievements. The 12th century stands beside the 18th as one of the greatest creative centuries in human history. The 13th like the 15th applied these creations in the transformation of society. The century of Dante was also that of the first English parliament; its vast economic expansion enabled the national state to triumph in both England and France, and furnished the grounds for the overthrow of Boniface VIII. Into the complex history of this momentous age it is impossible to go in any detail. Sufficient to say that in the opening quarter of the 14th century England and France at least stood on the brink of "modern times." Then these two nations entered upon that long tragedy of the Hundred Years' War, a calamity absolutely immeasurable to both. But during its massacres, juggernauts, plagues and famines, the cities of Italy, growing rich with trade and manufactures, were in their turn...
the centres of progress, this time in a new direction, toward the recovery of the antique past and the development of art.

This is the so-called Renaissance (q.v.). The humanists, who, produced, interested only in its splendid revelations, forgot or ignored the achievements of the period which intervened between Cicero and Petrarch. Then by the genius of their work they fastened their mistaken perspective upon historians and the cultured world at large. They struck upon the unfortunate and opprobrious term "middle ages" for that which stood between them and their classic ideals. The term was first used in this sense by Flavio Biondo, whose "decades" was an attempt to block out the annals of history from 510 to 1410. His treatment fell in admirably with the ideas of his age and of that following. To Protestants the age of the papal monarchy was like the reign of Anti-Christ. Then, after the indifference of humanists and Protestant polemic, came the disgust of men of science at the scholastic philosophy—an attitude best exhibited in Bacon's "Advancement of Learning." The 18th century was thus trebly barred from knowledge of genuine medieval history. Romanticism, that reaction in which Sir Walter Scott, the Schlegels, and Victor Hugo so largely figured, was as far from understanding what it admired as classicism had been from what it hated. Its extravagant praise of all that savoured of the middle ages carried it to the rest of the world and for it, the ages of romance and chivalry. The view of the romantics was as one-sided as any that had gone before. It is only with the introduction of a wider outlook in the scientific study of history that it has been possible to straighten the perspective and modify the traditional scheme.

In the purely intellectual sphere it is certainly true that the recovery of the antique world was of great importance; that it made possible genuine criticism by presenting new points of contrast and opening up fields that led away from theological quibbles. But it did not mean the "double discovery of the outer and inner world." Mankind did not, as Burckhardt and J. A. Symonds lead one to imagine, suddenly throw off a cowl that had blinded the eyes for a thousand years to the beauty of the world around, and awaken all at once to the mere joy of living. If any one was ever awake to the joys of living it was the minnesinger, troubadour or goliard, and the world had to wait until Rousseau and Burns before its external beauty was discovered, or at least deeply appreciated, by any but a few Dutch artists. Even Goethe crossed the Alps with his carriage closed. But the French, with Blanqui, Montesquieu, and Montesquieu, the revolutionaries until after the middle of the 18th century. The discovery of the outer world is a recent thing in art as well as in science. As for the claim that the "Renaissance" delivered men from that blind reliance upon authority which was typical of "medieval" thought, that is a fallacy cherished by those who themselves rely upon the authority of historians, blind to the most ordinary processes of thought. In this regard, indeed, in spite of the advance of scientific method and the wealth of material upon which to base criticism, we are still for the most part in the middle ages. The respect for anything in books, the dogma of journalistic inerrancy which still numbers its devotees by millions, the common acceptance of even scientific conceptions upon the dicta of a small group of investigators, these are but a few of the signs of the persistence of what is surely not a medieval but a universal trait. The so-called Renaissance did much; but it did not do the things attributed to it by those who see the "middle ages" through humanist glasses.

Upon the whole, therefore, it would seem that not only was there no middle age common to all branches of human evolution, except the period more definitely marked, no dark age, but that those characteristics which are generally regarded as "medieval" were by no means limited to a single epoch of European history. In short, the dark age was a reality; but the traditional "middle ages" are a myth. (J.T.S.)

MIDDLEBORO, a township of Plymouth county, Massachusetts, U.S.A., in the S.E. part of the state, bounded on the N.W. by the Taunton river. Pop. (1850), 6065; (1900), 6885—of whom 920 were foreign-born; (1910 census) 8214. Area, about 70 sq. m. The principal village also is named Middleboro; it is 35 m. S. of Boston, is served by the New York, New Haven & Hartford railroad and by electric lines connecting with Taunton, Boston, New Bedford and Cape Cod, and has a town-house, a soldiers' monument, and a public library housed in a building erected from a fund (part of which is used as a permanent endowment) bequeathed by Thomas Sprout Peirce (1823-1901), a merchant of the township, who, in addition, bequeathed about $500,000 as a special trust-fund for the use and benefit of the town of Middleboro; the income has been spent largely in the construction of macadam roads, the erection of an almshouse and the installation of special courses in the high school. The village, a place of considerable natural beauty, is a summer resort, and has various manufactures. Other villages in the township are North, East and South Middleboro, and Rock. The township had important herring fisheries in early times and manufactured straw hats (from 1828) and ladies' dress goods. Middleboro was settled about 1662 under the Indian name Nemasket; became a part of the township of Plymouth in 1663; and in 1669 was incorporated as a separate township, taking its name probably from Middleborough, North Riding, York.

MIDDLETOWN, a village and the county-seat of Addison county, Vermont, U.S.A., in Middletown township, on Otter creek, about 31 m. N.N.W. of Rutland. Pop. of the village (1850), 1762; (1900), 1807 (221 foreign-born); (1910), 1866; of the township, (1900), 3045; (1910), 2848. Middletown is served by the Rutland railroad. It is picturesquely situated near the Green Mountain range, and is the seat of Middlebury College (chartered, 1800; coeducational since 1883), which offers a classical course and a Latin-scientific course, and had in 1907-1908 12 instructors and 203 students (84 of whom were women), and a library of 35,000 volumes. The Sheldon art museum and a public library are among the public institutions of the village, and the principal buildings include the court-house and the opera-house. The principal industrial establishments are marble quarries, "Italian" marble works, iron foundries, lime-kilns, flour-mills, and door, sash and lumber mills. About 1 m. north of the village, in the township of Weybridge, there is a large United States government breeding station for Morgan horses, and merino sheep are raised in the vicinity.

The township of Middlebury was incorporated in 1761, and the first settlement on the site of the present village was made in 1773. At the outbreak of the War of Independence the settlement was deserted, and all except two or three of the houses were destroyed by British troops; but the settlers returned soon after the close of the war, and the township was formally organized and sent a member to the state assembly in 1788. Middlebury was incorporated as a borough in 1813, and as a village in 1832.

MIDDLEBROUGH, a municipal, county and parliamentary borough and seaport in the North Riding of Yorkshire, England, 2388 m. N. by W. from London, on the North Eastern railway. Pop. (1851), 75,532; (1901), 97,302. It lies on the south bank of the Tees, 5 m. from its mouth in the North Sea, and is the centre of one of the most important iron-working districts in the world. It is wholly of modern growth, having been incorporated in 1853. Its chief buildings are a fine town-hall with lofty clock-tower and spire (1880), containing the municipal offices, free library, &c.; the exchange, county court, Dorman memorial museum and Roman Catholic cathedral. Besides iron and steel works, the first of which was that of Baynton, 1853, there are numerous engineering works, oil works, chemical works, salt works and a considerable shipbuilding industry. The district abounds in blast furnaces. The docks are accessible to large vessels, the entrance having a depth of 32 ft. Extensive dredging operations are carried on in the river. The accommodation for shipping includes two grading docks, two patent slips, &c. The entrance to the river is protected by two breakwaters named respectively the North Gare and South Gare. The furnaces within the port produce some
2,500,000 tons of pig iron annually. Middlesbrough is the seat of a Roman Catholic bishop. The parliamentary borough falling within the Cleveland division of the county, returns one member. The county borough was created in 1888. The town is governed by a mayor, ten aldermen and thirty councillors. Area, 2823 acres.

The earlier history of the place is meagre. Where Middlesbrough now stands there were at one time a small chapel and priory founded by Robert de Brus of Skelton Castle. These were dedicated to St Hilda, and with some lands were given by de Brus to the abbey of St Hilda at Whitby in 1130. The priory fell into ruins at the time of the Reformation, and no trace now remains beyond some stones built into the wall of a brewery. The Oak Chair in the town-hall also is made from a fragment. In 1801 there were upon the site of Middlesbrough only four farmhouses. In 1829 a company styling itself the Middlesbrough Owners bought 500 acres of land, and began building in the town. In 1830 the Stockton & Darlington railway was extended to Middlesbrough; four years later the town was lighted with gas; and after six years more a public market was established. The census of 1831 showed the population to be 154; that of 1841 showed 5709. In 1842 the opening of the docks gave additional importance to the town. From the year 1851, when John Vaughan was elected its first member, the presence of ironstone in the Eston hills, the town advanced rapidly.

**MIDDLESEX, LIONEL CRANFIELD, 1st EARL OF (1575-1645),** was a successful London merchant, who was introduced to King James I. by Henry Howard, earl of Northampton, and entered the royal service in 1605. In 1613 he was knighted and was appointed surveyor-general of customs; in 1616 he became one of the masters of requests, and in 1619 master of the court of wards and liveries and chief commissioner of the navy. He was returned to parliament as member for Hythe in 1614 and for Arundel in 1621. Cranfield, who was also master of the wardrobe, was responsible for many economies in the public service, and his business acumen was very useful to the king. He took part in the attack on Bacon in 1621, and although, contrary to general expectation, he did not succeed Bacon as lord chancellor, he was created Baron Cranfield in July of this year. In 1621 also he became lord high treasurer, and in September 1622 was created earl of Middlesex, losing his positions and influence shortly afterwards because he opposed the projected war with Spain, and had incurred the hostility of Prince Charles and George Villiers, duke of Buckingham. Impeached by the House of Commons for corruption, he was found guilty by the House of Lords in May 1624 and was sentenced to lose all his offices, to pay a heavy fine and to be imprisoned during the king's pleasure. However, he was released from prison in a few days, was pardoned in the following year, and was restored to his seat in the House of Lords in 1640. The earl's second wife was Anne Brent (d. 1670), a cousin of Buckingham's mother, whom he married somewhat reluctantly in 1621 in order to ensure Buckingham's support. Middlesex died on the 6th of August 1645, leaving with other issue a son James (1631-1651), 2nd earl of Middlesex, who was a partisian of the parliamentary party during the Civil War. James was succeeded by his brother, Lionel, and when this earl died in October 1674 his titles became extinct. The first earl's daughter Frances married Richard Sackville, 5th earl of Dorset, and their son Charles was created earl of Middlesex in 1675. Two years later he became earl of Dorset, and the title of earl of Middlesex was borne by the earls and dukes of Dorset until 1843.

**MIDDLESEX,** a south-eastern county of England, bounded N. by Hertfordshire, E. by Essex, S.E. by the county of London, S. by Surrey, and W. by Buckinghamshire. The area is 2833 sq. m., and, excepting Rutland, the county is the smallest in England. The area outside the county of London, or extra-metropolitan area, with which this article is mainly concerned, is 2338 sq. m. It lies entirely in the basin of the river Thames, which forms its southern boundary. On the east it is separated from Essex by the Lea, the largest northern tributary of the Thames. The other rivers, in order westward, are the Brent, the Crane or Yeddin Brook, and the Colne. The waters of several streams are collected in the artificial Brent reservoir near Hendon, from which the Brent flows with a circuosity course to the Thames at Brentford. The Crane, rising in the ground south of Richmond, joins the Thames at Tedworth, and the Colne, which rises on the south-west, enlarge between Watford and St Albans (Hertfordshire), traverse a flat valley on the western boundary of the county, where it divides into several channels, and joins the main river at Staines. The highest ground, exceeding 400 ft. at several points, and reaching 503 ft. above Stanmore, is found along the northern boundary, in a line from Stanmore through Elyseer, Chipping Barnet and Potter's Bar. Two well-marked lines of heights, detached from the main line, project southward, the eastern from Whetstone through Finchley and Highgate to Hampstead, where, within the county of London, a height of 443 ft. is found on Hampstead Heath; the western being the isolated elevation on which stands Harrow-on-the-Hill. The hills skirting the Lea valley, in the neighbourhood of Enfield, are abrupt, though of no great elevation. Elsewhere the country is very slightly undulating or quite flat, as along the banks of the Thames and Lea. The Thames, however, beautifies its immediate neighbourhood, and rich sylvan scenery is not wanting in the higher districts. The greater part of the county was formerly densely forested and the northern counties, though now more open to the population, still preserve in the north-east, still recalls this condition. In modern times the visible influence of London has spread over practically the entire county. Villages have grown into populous suburbs; large institutions, for which sites adjacent to rather than within the metropolis have been found preferable, are numerous, and the development of suburban railway communications has brought fresh ground within reach of builders.

**Geology.**—The county lies entirely within the structural basin of the Thames, and, as in the neighbouring counties, the general slope of the ground and dip of the strata is towards the south-east. The area is a large and of a regular form, its sides being bordered by, on the left, the river Thames, on the right by the heavily built-up area of London, and, by Hanwell and Ealing to Hyde Park and east of a similar line from the upper side of the Park to Tottenham and on from that point to Enfield, the only visible deposits are the gravels, loams, brickclays, and sands lying in thin layers above the ironstone. The deposits between the gravels, and to the east of them, are evidence of the alluvial boundary indicated above. It gives rise to the undulating grassy country round Harrow, Chipping Barnet and Elstree. Below the London clay are the sandier Reading beds, they may be seen on the Heath and south of Middlesex; they are especially visible at Pinner and Ruislip. Chalk is only visible on the southern outskirts of the Colne valley at Harcawel, where it is quarried, and at South Mimms. Formerly, the sandy and pebbly Bagshot beds covered all the London clay area, but now only isolated patches remain, such as those on the top of the Pleistocene island at Ealing. Except in the Bagshot beds were laid down the country was covered by a variety of glacial deposits; such are the pebble gravels of Stanmore Heath and the district north of Barnet, the clay and sand of Finchley, Muswell Hill, and Southgate, the sand and clay of South Mimms, of Southgate and Potter's Bar. Several deep borings in the London basin prove the existence, beneath the chalk, of beds which do not crop out in Middlesex. The most interesting is that of the Thames embankment; it passes through the following formations: gravel and clay, 21 ft.; London clay, 64 ft.; Reading beds, 51 ft.; Thanet sand, 21 ft.; chalk, 655 ft.; upper greensand, 28 ft.; gault, 160 ft.; lower greensand, 400 ft.; Devonian rocks, 500 ft.; &c., &c.

**Industries.**—The climate of some of the high-lying districts is particularly healthy. Little more than one-half the total area of the county is under cultivation; and the grain crops, greatly decreasing, are insignificant. The soil in the north and north-west

---

2 A large model of the geology of London is exhibited in the Museum of Practical Geology, Jermyn Street, London.
Middleton, Earls of

is heavy, poor clay; but the rich alluvial soil of the Thames Valley is specially suitable for market gardens. On the outskirts of London much land now built over was formerly devoted to market gardening. The number of livestock decreases; in fact, agriculture as a whole has dwindled; industries that are based on it are of little account. But extensively and varied. The county is naturally, in view of the proximity of London, closely intersected with railways, the following companies, from east to west and south, affording communication to the Great Northern, Great Eastern, Great Western, Metropolitan Great Central, Metropolitan District, Great Western, London & South-Western. Moreover, in some parts the tramway system has been extended over a wide area from London; in others it has been abandoned, at the cost of much expense. The principal canals are the Grand Junction, running west from Brentford to the Colne Valley, and thence northward; with a branch (the Paddington Canal) connecting it with the Regent's Canal in London; and, in the east, the Lea navigation.

Parish Registration and Administration. The area of the ancient county is 181,320 acres, with a population in 1871 of 2,539,765; in 1901 of 3,251,671; and in 1901 of 3,585,323. At the time of the Domesday Survey the population of Middlesex, exclusive of London, was 2306. The extra-metropolitan area is 149,696 acres, with a population in 1901 of 798,738. The part of the ancient county which was transferred to the county of London under the Local Government Act 1888 was 37,464 acres in extent, and 771 acres were then transferred to Hertfordshire; while under the London Government Act 1899 the southern part of Horsley was transferred to London. The area of the administrative county is 148,700 acres. The county contains six hundreds. The municipal boroughs are Ealing (pop. 33,931), Hounslow (22,450), Heston (15,171), Ealing (20,819), Teddington (15,711), Mitcham (13,965), Mitcham (9,865), Greenford (819), Hamiton (6813), Hampton Wick (2066), Hanwell (10,115), New Malden (9,441), Reigate (7,300), Staines (6,685), Sunbury-on-Thames (5,444), Teddington (13,057), Tooley (19,601), Twickenham (12,827), Uxbridge (11,418), Wealdstone (9,001), Wembley (4519), Willesden (11,418), Wood Green (34,233). The county is in the jurisdiction of the central criminal court, and the whole extra-metropolitan county is within the manorial jurisdiction of the Great Ossulston of Middlesex. There are one court of quarter sessions and eight petty sessional divisions. The number of civil parishes is 60. Middlesex (extra-metropolitan) is wholly in the diocese of London, excepting a small portion in that of Oxford, and includes 26 ecclesiastical parishes for districts, wholly or in part. The extra-metropolitan parliamentary divisions, each return one member, are Ealing, Tottemham, Hornsey, Harrow, Uxbridge, Brentford and Ealing.

History.—The district which is now Middlesex was colonized by the Saxons in the 6th century by an offshoot of the East Saxon tribe, and derived its name from its position between the kingdoms of the East and West Saxons. In a charter dated 704 Middlesex is mentioned by name as a dependency of Essex, but soon after it acknowledged the supremacy of Mercia, and from 748 onwards the Mercian council was held at London, and from 780 onwards at Brentford. In the 9th century Middlesex formed part of the Danelagh, and in 993 Anlaf the Dane came with 93 ships to Staines. The only reference to Middlesex in the Saxon Chronicle occurs in 1011, when it was again overrun by the Danes. The Conqueror's march upon London was preceded by a general devastation of the surrounding country, the effects of which are illustrated in the Domesday Survey by the diminution in land values. At this time the district north of London formed the vast forest of Middlesex, the greater part of which was disafforested in the reign of Henry III. Enfield had woodlands for 2000 pigs; Ruislip for 1500 pigs; and Kingsbury, Hillingdon and Uxbridge for 1000 pigs each. In 1118 the priory of Latimer was founded at Holborn, Colham, Kempton and Kensington; fish ponds at Hammondsworth and Harrefield produced each 1000 eels.

As a shire Middlesex probably originated about the time of the frith of 886, when it is described as the land dependent upon London, and in 912 is referred to as "London and the land which owed obedience thereto." During the Saxon period the extensive manors held by the church of Canterbury, the bishop of London and his canons of St Paul's, and the abbey of Westminster were held as independent franchises, the courts for St Paul's being held at Stepney and Fulham, for Westminster at Westminster and Staines, and for Canterbury at Harrow. By charter of Henry I. (confirmed by Stephen and Henry II.) the citizens of London held Middlesex at farm for £300, with power to elect a sheriff from among their number, and by charter from John the shrievalty of both London and Middlesex was granted to the lord mayor and citizens in fee. By charter of 1242 the common pleas for the county of Middlesex were ordered to be held at the stone cross in the Strand. Under a charter of 1447 the lord mayor was authorized to nominate one of the city aldermen as justice of the peace for Middlesex. The six modern hundreds of Edmonton, Ealorne, Gore, Isleworth, Osulston, and Spelthorne have been scarcely changed since the Domesday Survey, except that Isleworth was then Honeslaw (Hounslow), while in the 12th century higher a hundred of "Mimes" is mentioned, corresponding with the Domesday hundred of Edmonton. Middlesex has always been included in the diocese of London. The archdeaconry of Middlesex, which includes part of Essex, is mentioned in 1151, but the Middlesex portion was not subdivided into rural deaneries until 1857, when the deaneries of Fulham, Ealing, Uxbridge, Staines, Hampton, Enfield, Harrow and St Pancras were created. The deaneries of Chelsea, Hammersmith, Hampstead, Hoxney, Ken- sington, Paddington, St Marylebone, Westminster and Willesden were created later, but Staines was abolished.

In 1625 Middlesex was ruled by William, earl of Salisbury, and Falke de Breauté, and in the same year at Runnymede near Staines John was forced to issue the Magna Carta. In the Civil War of the 17th century Middlesex supported the Parliamentary cause, joining in 1642 with Hertfordshire and Essex in a petition that the votes of the bishops and popish lords might be disallowed in the House of Lords, and that the forts and castles of the kingdom might be placed in such hands as the Parliament could confide in. Sir Denzil Hollis was defeated by the Royalists at Brentford in 1642, and in 1645 a fruitless treaty between Charles I. and the Parliament was concluded at Uxbridge. Brentford had famous election contests in 1768 and 1769.

The woollen and leather industries flourished in Middlesex in Norman times. London was the great place of slaughter, and hides were tanned at Enfield. Bricks were also manufactured from early times, and Heston was noted for its wheat. Paper was extensively manufactured in the 17th century, and much distress was caused in 1656 by a decree prohibiting the purchase of old rags for the Middlesex paper-mills for fear of the plague. In 1650 the manufacturers of rags in Middlesex appealed against a bill prohibiting the wearing of material made of the said yarn during the winter season. In 1655 a certificate of a hundred master tanners and other traders of Middlesex approved an invention for converting raw hides into leather by means of new liquor, with or without oak-bark.

Middlesex returned two members to parliament in 1295.

(For the representation of London, see LONDON.)

See John Norden, Speculum Britanniae: the parte firste, an histori- cal and chorographical description of Middlesex (London, 1593; reprinted 1637 and 1723); Daniel Lysons, The Environs of London (1792-1795); Victoria County History, Middlesex.

Middleton, Earls of. John Middleton, 1st Earl of Middleton (c. 1609-1747), belonged to a Kincairdinesh family who had held lands at Middleton since the 12th century. In early life he served as a soldier in France; later he fought against Charles I. both in England and in Scotland, being especially prominent at the battle of Philiphaugh and in other operations carried on against the great Montrose. He held a high command in the Scottish army which was then engaged against the king in 1648, and he was taken prisoner after the battle of Preston. He joined Charles II. when that monarch reached Scotland in 1650, but he was then soon at variance with the party which at that time was dominant in church and state and was only restored to favour after doing a public penance at Dundee. He was a captive for the second time after the battle of Worcester, where he commanded the Royalist cavalry, but he escaped from the Tower of London to Paris. In 1653 Middleton was chosen by Charles II. to head the projected rising in Scotland. He reached that country in February 1654, but the insurrection was a complete failure. Its leader, who cannot be held responsible for this result, remained in Scotland until 1655, when he rejoined Charles II., who made
him an earl in 1656. He returned to England with the king in 1660 and was appointed commander-in-chief of the troops in Scotland and lord high commissioner to the Scottish parliament, which he opened in January 1661. He was an ardent advocate of the restoration of episcopacy, this being one reason which led to serious dissensions between the earl of Lauderdale and himself, and in 1665 he was deprived of his offices. He was afterwards (1667) governor of Tangier, where he died in June 1674.

His eldest son CHARLES, 2nd EARL OF MIDDLETON (c. 1640-1710), held several offices under Charles II. and James II., being envoy extraordinary to Vienna and afterwards joint secretary for Scotland. In 1684 he became an English secretary of state, and with Richard Graham, Viscount Preston, he had the difficult task of managing the House of Commons for James II. He was loyal to James after the king fled to France, although he remained in England, where, as the leader of the moderate Jacobites, he sought to bring about a restoration by peaceful means.

In 1693 the earl joined the exiled king at St Germain, where he became his secretary of state; afterwards he held the same office at the court of James Edward, the old pretender, in Flanders and on the Continent. He was partly responsible for the unsuccessful expedition of the Jacobites to Scotland in 1707, and he resigned his office as secretary in 1713. Middlesex, who had been created earl of Monmouth by the pretender, died in 1710. His titles had been declared forfeited in 1695, but they were claimed by his son John, who died unmarried about 1746. The earl was a Protestant, although a lukewarm one, until 1701, when he yielded to the dying wish of James II. and joined the Roman Catholic Church.

One of Middleton's kinmen was Sir Charles Middleton, Bart. (1726-1813). Having served in the navy Middleton was comptroller of the navy from 1778 to 1790, "standing out through that period of inept administration as the pillar of the service." In April 1805, at a most critical time, he was, although eighty years of age, appointed first lord of the admiralty by Pitt and was created Lord Barham. It has been usual to regard Barham as a cipher at the admiralty board, but more recent research, especially an examination of the Barham Papers, has proved this to be the reverse of the truth. He enjoyed the absolute confidence of Pitt, and it was this confidence, industry, and energy which made possible the great campaign which ended at Trafalgar. He resigned office in January 1806 and died on the 17th of January 1813. His barony passed through his daughter Diana (1762-1823) to the Noels, earls of Gainsborough, by whom it is still held. The Barham Papers are being edited by Sir J. K. Laughton (vol. i. 1907; vol. ii. 1910). See also J. S. Corbett, The Campaign of Trafalgar (1910). See A. C. Biscoe, The Earls of Middleton (1870).

MIDDLETON, ARTHUR (1742-1787), American politician and signer of the Declaration of Independence, was born at Middleton Place on the Ashley river, South Carolina, on the 26th of June 1742. His family was one of the most prominent in the colony. The grandfather, Arthur Middleton (1687-1737), was president of the Council in 1725-1730 and as such was acting governor in 1725-1730, and the father, Henry Middleton (1717-1784), was speaker of the Assembly in 1745-1747 and again in 1754-1755, a delegate to the Continental Congress in 1774-1776, and its presiding officer from October 1774 to May 1775, a member of the South Carolina Committee of Safety, and in 1783 president of the South Carolina Provincial Congress. Like most wealthy South Carolinians of the 18th century, Arthur Middleton was educated in England—at Hackney, at Westminster School, and at St John's College, Cambridge. He then returned to South Carolina, but soon afterwards went back to England to live, and travelled on the Continent. In 1773 he again returned to South Carolina, and in the controversies between the colonists and the home government became a leader of the Whigs. He was a member of the provincial Council of Safety in 1775-1776, and a delegate to the Continental Congress in 1776-1777. In 1778 he was elected governor of South Carolina, but owing to his dissatisfaction with the new state constitution he declined to serve. He was captured by the British at Charleston in May 1780, was exchanged in July 1781, was again a delegate to Congress in 1781-1783, and later served in the state legislature. He died on the 1st of January 1785 at Middleton Place, near Charleston. His eldest son, Henry Middleton (1728-1846), was an orator of ability, was governor of South Carolina in 1810-1812, a representative in Congress in 1815-1819, and the United States minister to Russia from 1820 to 1830, negotiating in 1824 a convention "relative to navigation, fishing and trading in the Pacific Ocean, and to establishments on the North-West Coast." This was the first treaty between the United States and Russia.

MIDDLETON, CONVERS (1683-1750), English divine, was born at Richmond in Yorkshire on the 27th of December 1683. He graduated at Cambridge, took orders, and in 1706 obtained a fellowship, which he soon resigned upon contracting an advantageous marriage. In 1717 a dispute with Richard Bentley, who made an extortiionate demand on the occasion of Middleton's being created D.D., involved him in an acrimonious controversy. He wrote several trenchant pamphlets, among them the "Remarks" and "Further Remarks" on Bentley's Proposals for a New Edition of the Greek Testament, an undertaking to visit his grievances upon the text of the New Testament. In 1723 he was involved in the controversy with Bentley over the authenticity of the book of Enoch, which had found their way into his other judicial tract on literal and allegorical interpretations, written on the occasion of his appointment as university librarian.

In 1724 he defended the medical profession by a dissertation contending that the healing art among the ancients was only exercised by slaves or freedmen. Between the dates of these publications he visited Italy, and made those observations on the pagan origin of church ceremonies and beliefs which he subsequently embodied in his Letter from Rome (1729). This cogent tract probably contributed to prepare the storm which broke out against him on his next publication (1731). In his remonstrance with Daniel Waterland on occasion of the latter's reply to Matthew Tindal's Christianity as Old as the Creation, Middleton takes a line which in his day could hardly fail to expose him to the reproach of infidelity. He gives up the literal truth of the primeval Mosaic narratives; and, in professing to indicate a short and easy method of confuting Tindal, lays principal stress on the indispensableness of Christianity as a mainstay of society. This was to resign nearly everything that divines of the Waterland school thought worth defending. Middleton was warmly assailed from many quarters, and retreated with some difficulty under cover of a sheaf of apologetic pamphlets and a more regular attendance at church. His next important publication was a Life of Cicero (1747), largely told in that statesman's own words. Though Middleton's reputation was much enhanced by this piece of work, there is no doubt that he drew largely from the scarce book of William Bellenden, De tribus luminibus Romanorum. The work was undertaken at the instance of Lord Hervey, in correspondence with whom also originated his discretion on The Roman Senate, published in 1747. The same year and the following produced the most important of all his writings, the Introductory Discourse and the Free Inquiry "concerning the miraculous powers which are supposed to have subsisted in the church from the earliest ages." In combating this belief Middleton indirectly established two propositions of capital importance. He showed that ecclesiastical miracles must be accepted or rejected as a mass; and he distinguished between the authority due to the fathers' testimony to the beliefs and practices of their times, and their very slender credibility as witnesses to matters of fact. Some individual grudge seems to have prompted him to expose, in 1750, Bishop Sherlock's eccentric notions of antediluvian prophecy, which had been published 25 years before. On the 28th of July 1750 he died at Hildersham, near Cambridge.

Middleton's most ambitious work is obsolete from lack of fault of his, but his controversial writings retain a permanent place in the history of opinion. In his more restricted sphere he may not inappropriately be compared with Lessing. Like Lessing, the character of his intellect was captious and iconoclastic, but redeemed from mere negation by a passion for abstract truth, too apt to slumber until called into activity by some merely personal stimulus. His dictum is generally masculine and...
MIDDLETON, T.,

shocked as well as physically horrified by revelation of the real motive which impelled her accomplice into crime, gives a lurid streak of tragical humour to the lifelike interest of the scene; as the pure infusion of spontaneous poetry throughout redeems the whole work from the charge of vulgar subservience to a vulgar taste for the presentation or the contemplation of criminal horror.'

Leigh Hunt thought that the character of De Flores, for effect at once tragical, probable and poetical, "surpassed anything with which he was acquainted in the drama of domestic life." The underplot of the piece, though it is based on the humours of a madhouse, has genuine comic flashes. The Spanish Gipsy has a double plot based on the Fuerza de la sangre and the Gitana de Cervantes. Much has been said on the collaboration of Middleton with Rowley, who was much in demand with fellow-dramatists, especially for his experience in low comedy. These plays, even in scenes where the evidence in favour of one or other of the collaborators is not positive, show that neither the dramatist was able to achieve alone. It was clearly no mechanical partnership the limits of which can be said to be definitely assigned when the actual text has been parcelled out between the collaborators.

With Thomas Dekker he wrote The Roaring Girl, or Moll Cut-Purse (1611). The frontispiece represents Moll herself in man's attire, indulging in a pipe of tobacco. She was drawn or idealized from life, her real name being Mary Frith (1584-1659?), who was made to do penance at St Paul's Cross in 1612. "Worse things, I must confess," says Middleton in his preface, "the world has taxed her for than has been written of her; but 'tis the excellency of a writer to leave things better than he finds 'em." In the play she is the champion of her sex, and is equally ready with her sword and her wits. Middleton is also credited with a share in Thomas Dekker's Honest Whore (pt. i, 1604). The Witch, first printed in 1778 from a unique MS., now in the Bodleian, has aroused much controversy as to whether Shakespeare borrowed from Middleton or vice versa. The dates of both plays being uncertain, there are few definite data. The distinction between the two conceptions has been finely drawn by Charles Lamb, and the question of borrowing is best solved by supposing that what is common to the incantations of both plays was a matter of common property. The Mayor of Quinborough was published with Middleton's name on the title-page. In 1657, Sir Francis Bennet, the comic mayor, is not a very prominent character in the plot, which deals with Vertigier, Hengist, Horsus and Roxena among other characters. One of its editors, Mr Havelock Ellis, thinks the proofs of its authenticity as Middleton's work very slender. It is generally supposed to have been a very early work subjected to generous revision.

The plays of Middleton still to be mentioned may be divided into romantic and realistic comedies of London Life. Dekker had as wide a knowledge of city manners, but he was more sympathetic in treatment, reader to idealize his subject. Two New Plays. Viz.: More Dissemblers besides Women. Women beware Women, of which the former was licensed before 1622, appeared in 1657. The plot of Women beware Women is a double intrigue from a contemporary novel, Hypothesis and Isabella, and the genuine history of Bianca Capello and Francesca de Medici, this play, which ends with the massacrings when, at the end of Elizabethan drama, may be taken as giving the measure — no mean one — of Middleton's unaided power in tragedy.

The remaining plays of Middleton are: Blurt, Master-Constable, Or, the Spaniard's Blurt (1602); Michaelmas Term (1607), described by A. C. Swithinbank as an excellent Hoggarian comedy; The Phoenix (1607), a version of the Haroun-al-Raschid trick; The Famelie of Love (1608); A Trick to catch the Old-one (anonously printed, 1608); Your Five Goldens (licensed 1608); A Mad World, my Sworne Brother and Exemplum by the same author (1630); quite probable for the picture of Tim, the Cambridge student, on his return home; Anything for a Quiet Life (c. 1617, printed 1662); No Wit, No Help like a Woman's (c. 1613, printed 1657); The Widdow (printed 1647); The little page of which appear also the names of Ben Jonson and John Fletcher, though their collaboration may be doubted. Eleven of his names are extant. A tedious poem, The Wisdom of Solomon paraphrased, by Thomas Middleton, was printed in 1587, and M. Clefs, in Six Smalld Scowtes by T. M. Gent, in 1599. Two prose pamphlets, dealing with London life, Father Hubbard's Tale and The Black Book, appeared in 1604 under his initials. His non-dramatic work, however, even if genuine, has little value.

harmonious. Pope thought him and Nathaniel Hooke the younger the only prose writers of the day who deserved to be cited as authorities on the language, Samuel Parr, while exposing his plagiarisms, heaps eulogiums on his style. But his best qualities, his impatience of superstition and disdain of mere external authority, are rather moral than literary.

The best general view of his intellectual character and influence is to be found in Sir Leslie Stephen's English Thought in the Eighteenth Century, ch. vi. A handsome edition of his works, containing several posthumous tracts, but not including the Life of Cicero, appeared in 4 vols. in 1752 and in 5 vols. in 1755.

MIDDLETON, THOMAS (c. 1570-1627), English dramatist, son of William Middleton, was born about 1570, probably in London. There is no proof that he studied at either university, but he may be safely identified with one of the Thomas Middletons entered at Gray's Inn in 1593 and 1596 respectively. He began to write for the stage with The Old Law, in the original draft of which, if it dates from 1593 as is generally supposed, he was certainly not associated with William Rowley and Philip Massinger, although their names appear on the title-page of 1656. By 1602 he had become one of Philip Henslowe's established playwrights. The pages of Henslowe's Diary contain notes of plays in which he had a hand, and in the year 1607-1608 he produced no less than six comedies of London life, which he knew as accurately as Dekker and was content to paint in more realistic colours. In 1613 he devised the pageant for the installation of the Lord Mayor, Sir Thomas Middleton, and in the same year wrote an entertainment for the opening of the New River in honour of another Middleton. From these facts it may be reasonably inferred that he had influential connexions. He was frequently employed to celebrate civic occasions, and in 1620 he was made city chronologer, performing the duties of his position with exactness till his death.

The most notable event in his career was the production at the Globe theatre in 1624 of a political play, A Game at Chess, satirizing the policy of the court, which had just received a rebuff in the matter of the Spanish marriage, the English and Spanish personages concerned being disguised as the White Knight, the Black King, and so forth. The play was stopped in consequence of remonstrances from the Spanish ambassador, but not until after nine days' performances, and the dramatist and the actors were summoned to answer for it. It is doubtful whether Middleton was actually imprisoned, and in any case the king's anger was soon satisfied and the matter allowed to drop, on the plea that the piece had been seen and passed by the master of the revels, Sir Henry Herbert. Middleton died at his house at Newington Butts, and was buried on the 4th of July 1627.

He worked with various authors, but his happiest collaboration was with William Rowley, this literary partnership being so close that F. G. Fleay (Biog. Chron. of the Drama) treats the dramatists together. The plays in which the two collaborated are A Fair Quarrel (printed 1617), The World Lost at Tennis (1620), an ingenious masque, The Changeling (acted 1624, printed 1653), and The Spanish Gipsy (acted 1623, printed 1633). The main interest of the Fair Quarrel centres in the mental conflict of Captain Ager, the problem being whether he should fight in defence of his mother's honour when he no longer believes his quarrel to be just. The underplot, dealing with Jane, her concealed marriage, and the physician, which is generally assigned to Rowley, was suggested by a story in Giraldi Cinthio's Hecatom- midès. The Changeling is the most powerful of all the plays with which Middleton is connected, being taken from the tale of Alsemero and Beatrice-Joanna in Reynolds's Triumphs of God's Reveng against Murder (bk. i., hist. iv.), but the story, black as it is, receives additional horror in Middleton's hands. The famous scene in the third act between Beatrice and De Flores, who has murdered Piracqua at her instigation, is admirably described by Swinburne:

"That note of incredulous amazement that the man whom she has just instigated to the commission of murder 'can be so wicked' as to have served her end for any end of his own beyond the pay of a professional assassin, is a touch worthy of the greatest dramatist that ever lived. . . . That she, the first criminal, should be honestly
MIDDLETOWN—MIDDLETOWN

AUTHORITIES.—His works were edited by Alexander Dyce (5 vols.) in 1840, with a valuable introduction quoting many documents, and by A. H. Bullein (8 vols.) in 1885. The Best Plays of Thomas Middleton were edited for the Mermaid series (1887) by Havelock Ellis with an introduction by A. C. Swinburne. See also Miss P. G. Wiggin’s Inquiry into the Authorship of the Middleton-Routley Plays (Boston, 1897), and the notice on Middleton in Professor A. W. Ward’s Hist. of Eng. Dram. Lit. (ed. 1899; ii., 493-540), which includes a catalogue of his plays. The article on Middleton at Chez S. A careful examination of the parallelisms between the plays of Shakespeare and Middletown is made by D. Hugo Jung in “Das Verhältnis Thomas Middletons zu Shakespeares” (Münchener Beiträge zur roman. u. engl. Phil. vol. xlix, 1904).

MIDDLETOWN, a market town and municipal borough in the Middletown parliamentary division of Lancashire, England, on the Irk, near the Rochdale Canal, and on the Lancashire & Yorkshire railway, 6 m. N.N.E. from Manchester. Pop. (1901), 25,178. The church of St Leonards is of mixed architecture, with a low square tower. The oldest portion of the building (the tower arch) dates from the 12th century, but the main portion from 1412, and the south aisle from 1524. Two chapels in it contain memorials of, and are named after, two ancient Lancashire families, the Asshetons and the Hopwoods. The Queen Elizabeth grammar-school, a building in the Tudor style, was founded in 1572 by Nowell, dean of St Paul’s, London. There are a handsome town-hall and municipal technical schools. An extensive system of tramways and electric light railways connects the town with its suburbs and adjacent industrial centres. The prosperity of the town dates from the introduction of manufactures at the close of the 18th century. The staple trade is the spinning and weaving of cotton, and the other industries include silk weaving, calico-printing, bleaching, dyeing, iron-founding and the manufacture of soap and chemicals. There are collieries in the neighbourhood. The town was incorporated in 1886, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 4,775 acres.

MIDDLETOWN, a city and the county-seat of Middlesex county, Connecticut, U.S.A., in the township of Middletown, in the south central part of the state, on the west bank of the Connecticut river, about 30 m. from its mouth, and about 15 m. south of Hartford. Pop. (1890), 9,013; (1900), 9,589, of whom 2316 were foreign-born; (1910 census) 11,851. Within a radius of 2 m. from the city hall there was found in 1910 most of the township’s population of 20,749. The city is served by two branches of the New York, New Haven & Hartford railroad, by a line of coast steamers, and by electric lines connecting with neighbouring cities and villages. The city is connected by a long highway bridge with the village of Portland in the township of Portland (pop. in 1910, 3425; area 26 sq. m.), which is known for its brown-stone quarries. Four miles south of Middletown is Chestnut Mountain (or Bull Hill), which commands a fine view, and about 3 m. east are the “Narrows” of the Connecticut river, which contain a full account of Middletown’s Game of Cheese. A number of handsome residences. In High Street stand the buildings of Wesleyan university (Methodist Episcopal), founded in 1831 by the Rev. Wilbur Fisk, who became the first president and the Rev. Laban Clark (1778-1858), who became the first president of the board of trustees. Women were first admitted in 1872, but coeducation was later discontinued; and the last freshman class of women students under the old system entered in 1900. The university offers classical and scientific courses, and in 1908-1909 had 36 instructors, 322 students (30 being women), and a library of 79,000 volumes. In 1875-1877 the work of the first agricultural experiment station in the United States was carried on here under state supervision in Wesleyan University, with Professor Wilbur Olin Atwater (1844-1907) as director; it was then removed to New Haven. Middletown is also the seat of the Berkeley divinity school (Protestant Episcopal), founded in 1849 as the theological department of Trinity College, Hartford, and chartered and removed to Middletown in 1854, and in 1907 a faculty of 8, and 16 students; and the city has a school of medicine. Middletown has a free public library (1874) with 17,000 vols. in 1907. South-east of the city is the Connecticut hospital for the insane, and south-west of the city, the Connecticut industrial school for girls (reformatory). The total value of the factory products in 1905 was $5,004,576, an increase of 35% over that for 1900. The municipality owns and operates the waterworks.

Middletown occupies the site of an Indian village, Mattabesc or Mattabesett (from Massa-sepues-et, “at a great rivulet or brook”), the principal village of the Mattabesc Indians, an Algonquian tribe which included the Wongunk, Pyquag and Montowese Indians and seems to have had jurisdiction over the whole of southern Connecticut. The township of Middletown was settled by whites in 1659, and until 1673, when the present name was adopted, was known by the Indian name, Mattabesett. It was incorporated in 1651; and the city was chartered in 1784. Shipbuilding and commerce became the principal sources of wealth. In the middle of the nineteenth century Middletown was one of the leading cities of Connecticut, and as late as 1886 it was a port of entry; but the development of rival ports, especially New Haven, Hartford and Bridgeport, into railway centres, retarded the growth of manufacturing, and commerce declined after the Civil War.

MIDDLETOWN, a city of Orange county, New York, U.S.A., on the Wallkill river, 67 m. N.N.W. of New York City. Pop. (1890) 11,077; (1900) 14,529, including 1700 foreign-born and 480 negroes; (1905, state census) 14,516; (1910) 15,315. It is served by the Erie, the New York, Susquehanna & Western, and the New York, Ontario & Western railways, and is connected by an electric line with Goshen (pop. in 1910, 3081), the county-seat. It is situated in an attractive dairy and agricultural country; and in the city and vicinity there are many summer residences. Here are the state homoeopathic hospital for the insane, a state armoury, Thrall hospital, and Thrall library. Middletown is primarily a manufacturing city, and has the car shops of the New York, Ontario & Western railway. The value of its factory products increased from $1,154,742 in 1900 to $3,356,330 in 1905, or 55.8%. The municipality owns and operates its waterworks. Middletown was settled about 1796 and owed its early commercial importance to its being a “half-way house” (whence its name) for travellers on the Minisink Road to western New York, and it was for a time a terminus of the Erie railroad. It was incorporated as a village in 1848, and first chartered as a city in 1889.

MIDDLETOWN, a city of Butler county, Ohio, U.S.A., on the Miami river, 34 m. N. of Cincinnati. Pop. (1890), 7601; (1900), 9215, of whom 760 were foreign-born and 314 were negroes; (1910) 13,152. It is served by the Cleveland, Cincinnati, Chicago & St Louis, the Cincinnati, Hamilton & Dayton, the Cincinnati Northern (New York Central system), and a branch of the Cincinnati, Lebanon & Northern (Pennsylvania system) railways. It is the trade centre of a rich and beautiful agricultural region in which tobacco, wheat and Indian corn are the principal crops. The river furnishes considerable water-power and the total factory product in 1905 was valued at $8,357,993, an increase of 47.5% over that of 1900. The waterworks are owned and operated by the municipality. Middletown was laid out in 1802 and was named from its location between Cincinnati and Dayton; it was incorporated in 1833.

MIDDLETOWN, a borough of Dauphin county, Pennsylvania, U.S.A., on the east bank of the Susquehanna river, 9 m. below Harrisburg. Pop. (1890), 5080; (1900), 6068 (340 foreign-born and 289 negroes); (1910), 5374. It is served by the Pennsylvania and the Philadelphia & Reading railways, and by an electric line to Harrisburg. The borough has a considerable trade with the surrounding agricultural country, and owing to the proximity of the Yorkhaven power-plant (across the river) and the excellent railway service, is a manufacturing centre. The municipality owns its electric lighting plant. Middletown was founded in 1755 by Friends (from Philadelphia and other places in Pennsylvania) and Scotch-Irish, and was so named because of its position midway between Lancaster and Carlisle. It was first incorporated as a borough in 1828.

MIDDLEWICH, an urban district in the Northwich parliamentary division of Cheshire, England, 166 m. N.W. of London, XIX. 14
MIDHAT PASHA (1822–1834), Turkish statesman, the son of a civil judge, was born at Constantinople in 1822. His father, a declared partisan of reform, trained him for an administrative career, and at the age of twenty-two he was attached as secretary to Fakh Efendi, whom he accompanied in Syria for three years. On his return to Constantinople Midhat was appointed chief director of confidential reports, and after a new financial mission in Syria was made second secretary of the grand council. His enemies, however, succeeded in ousting him from this post, and caused him to be entrusted with the apparently impossible task of settling the revolt and brigandage rampant in Rumelia. His measures were drastic and their success was startling and the government made him an official of the first rank and restored him to his place in the grand council. In similar vigorous fashion he restored order in Bulgaria in 1857. In 1860 he was made vizier and pasha, and entrusted with the government of Nisch, where his reforms were so beneficial that the sultan charged him, in conjunction with Fuad Pasha and Ali Pasha, to prepare the scheme for adapting them to the empire which was afterwards known as the law of the vilayets. After further administrative work in his province, he was ordered to organize the council of state in 1866, and was then made governor of Bagdad, where his success was as decisive as at Nisch, but attended with much greater difficulties. In 1871 the anti-reform influence of the grand vizier, Mahmoud Nedim, seemed to Midhat a danger to the country, and in a personal interview he boldly stated his views to the sultan, who was so struck with their force and entire disinterestedness that he appointed Midhat grand vizier in place of Mahmoud. Too independent, however, for the court, Midhat remained in power only three months, and after a short governorship of Salonica he lived apart from affairs at Constantinople until 1875.

From this time forward, however, Midhat Pasha's career resolved itself into a series of strange and almost romantic adventures. While sympathizing with the ideas and aims of the "Young Turkey" party, he was anxious to restrain its impatience, but Midhat's obduracy led to a coalition between the grand vizier, the war minister and Midhat Pasha, which deposed him in May 1876, and he was murdered in the following month. His nephew Murad V. was in turn deposed in the following August and replaced by his brother, Abdul Hamid II. Midhat Pasha now became grand vizier, reforms were freely promised, and the Ottoman parliament was inaugurated with a great flourish. In the following February, however, Midhat was dismissed and banished for supposed complicity in the murder of Abdul Aziz. He then visited various European capitals, and remained for some time in London, where he carefully studied the procedure in the House of Commons. Again recalled in 1878, he was appointed governor of Syria, and in August exchanged offices with the governor of Smyrna. But in the following May the sultan again ordered him to be arrested, and although he effected his escape and appealed to the powers, he shortly afterwards saw fit to surrender and claim a fair hearing. The trial accordingly took place in June, when Midhat and the others were sentenced to death. It was, however, generally regarded as a mockery, and on the intercession of the British government the sentence was commuted to banishment. The remaining three years of his life were consequently spent in exile at Taif in Arabia, where he died, probably by violence, on the 8th of May 1884. To great ability, wide sympathies, and undoubted patriotism he added absolute honesty, that rare quality in a vizier, for he left office as poor as when he entered. (G. F. B.)

MIDHURST, a town in the north-western parliamentary division of Sussex, England, 12 m. N. by E. of Chichester by the London, Brighton & South Coast railway; served also by the London & South Western railway. Pop. (1901), 1764. It is pleasantly situated on slightly rising ground near the river Rother. The church of St Mary Magdalen and St Denis is a large Perpendicular building. The town retains several picturesque old houses, and in the vicinity, by the river, are the ruins of the 16th century mansion of Cowdray, burnt down in 1793. A grammar-school was founded at Midhurst in 1672 and attained some eminence. After being closed for many years it was reopened in 1880. In 1906 a magnificent sanatorium for consumptives was opened about 4 m. from Midhurst; it bears the name of King Edward VII., who laid its foundation stone and opened it. The name of Midhurst (Middleshert, Mudhurst) first occurs in the reign of Henry I., when Savaric Fitz-Cana held it of the honour of Arundel, then presumably in the king's hand.

The charter of Henry I., although no longer extant, is quoted in later confirmation charters of Richard I., Henry III., Edward III. and Richard II. Franco de Bohun inherited Midhurst from his uncle Savaric Fitz-Savaric, and the De Bohuns held the lordship until 1400 when Sir David Owen obtained it through his marriage with the daughter of the last male heir. He sold it to Sir William Fitz-William, from whom it passed to Sir Anthony Browne and descended to the viscounts Montague. Midhurst is definitely called a borough in the reign of Edward I., but the borough-court and market were probably in existence much earlier. It was governed by a bailiff, elected annually, until the office lapsed, probably early in the 13th century. In an act of 1883 it is mentioned as one of the towns which had long ceased to be municipal. No charter of incorporation is known. Midhurst returned two members to parliament from 1300–1301 till 1832, and from that date one member until 1885 when it was disfranchised. In the reign of Henry VI. a market was held by the burgesses every Thursday, and a fair on Whit-Tuesday, by grant from Sir John Bohun. In 1888 the fair-days were the 6th of April, the 9th of May, and the 29th of October. The market-day was Thursday. Pleasure-fairs are still held on the 6th of April and the 29th of October, but there is no market.

MIDIAN (properly Madyan, so Sept.), in the Bible, one of the peoples of North Arabia whom the Hebrews recognized as distant kinmen, representing them as sons of Abraham's wife Keturah ("incense"). Thus the sons of Keturah are the "incense-men," not indeed inhabitants of the far south incense-land, but presumably the tribes whose caravans brought the incense to Palestine and the Mediterranean ports. So the Midianites appear in connection with the gold and incense trade from Yemen (Isa. Ix. 6), and with the trade between Egypt and Syria (Gen. xxxvii. 28, 36). They appear also as warriors invading Canaan from the eastern desert, and ravaging the land as similar tribes have done in all ages when Palestine lacked a strong government (see GIDEON). Again, they are described as peaceful shepherds, and the pastures of the Midianites, or of the branch of Midian to which Moses's father-in-law (Jethro or Reuel, or Hobab) belonged, lay near Mount Horeb (Exod. iii. 1). The Kenites who had friendly relations with Israel, and are represented in Judg. i. 16, iv. 11, as the kin of Moses's father-in-law, appear to have been but one fraction of Midian which took a separate course from their early relations to Israel.1 Balaam, according to one version of the story, was a Midianite (Num. xix. 29, seq.) and his association with Moab has been connected with the statement in Gen. xxxvi. 35, that the Edomite king Hadad defeated Midian in the land of Moab; (see Balaam, Edom).
A place Midian is mentioned in 1 Kings xi. 18, apparently between Edom and Paran, and in later times the name lingered in the district of the Gulf of Aqaba, and the East can look a city Midian in the country of the Saracens and Ptolemies (vi. 7) places Modiana. Still later Midian was a station on the pilgrimage route from Egypt to Mecca, the second beyond Aila (Elath). Here in the middle ages was shown the well from which Moses watered the flocks of Sho’aib (Jethro), and the place is still known as “the caves of Sho’aib.” It has considerable ruins, which have been described by Sir R. Burton (Land of Midian, 1879).

This district which has on its east Taimik, a centre of civilization in the 5th century B.C., and on its south-east El-Ola whose existence as a seat of culture is possibly even older, is identified by some scholars with the Murad of the Midianite (south Arabian) inscriptions, on which see Sabaeans, Yemen. That this part of north-west Arabia had frequent intercourse with Palestine appears certain from its commercial relations with Gaza; and the association of the Midianite with early Hebrew legislation, as also the possibility that Mizraim (“Egypt”) in the Old Testament should be taken in some cases to refer to this district, have an important bearing upon several Old Testament questions. See Mizraim.

MIDLETON, WILLIAM ST JOHN FREMANTLE BRODRICK, 9th Viscount (1856–), English politician, was the son of the 8th viscount (1830–1907). He came of a Surrey family who in the 17th century, in the persons of Sir St John Brodrick and Sir Thomas Brodrick, obtained grants of land in the south of Ireland. Sir St John Brodrick settled at Midleton, between Cork and Youghal in 1641; and his son Alan Brodrick (1660–1728), speaker of the Irish House of Commons and lord chancellor of Ireland, was created Baron Brodrick in 1715 and Viscount Midleton in 1717 in the Irish peerage. In 1796 the title of Baron Brodrick in the peerage of the United Kingdom was created. The English family seat at Peper Harow, near Godalming, Surrey, was designed by Sir William Chambers. In 1844 Viscount Midleton was a Conservative and was returned for the borough of Cork for 8 years. He had a seat in the House of Commons, and was responsible in the House of Lords for carrying the Infants Protection Act. His brother, the Hon. G. C. Brodrick, was for many years warden of Merton College, Oxford. As Mr St John Brodrick, the 9th viscount had a distinguished career in the House of Commons. After being at Eton and Balliol, Oxford, and serving as president of the Oxford Union, he entered parliament as conservative member for one of the Surrey divisions in 1886. From 1886 to 1892 he was financial secretary to the war office; under secretary for war, 1895–1898; under secretary for foreign affairs, 1898–1900; secretary of state for war, 1900–1903; and secretary of state for India, 1903–1905. He lost his seat for the Guildford division of Surrey at the general election of January 1906. In March 1907 he was made an alderman of the London County Council. He married, first in 1880, Lady Hilda (d. 1901), daughter of the Hon. Wm. Wyndham of Wmwns, by whom he had a family; and secondly in 1903, Madeleine Stanley, daughter of Lady St Helier by her first husband.

MIDLETON, or MIDLETON, a market town of Co. Cork, Ireland, on the river Owenacurra, 13 m. E. of Cork by the Youghal branch of the Great Southern & Western railway. Pop. (1901), 3361. The river here enters a branch of Cork harbour. The surrounding hilly country is pleasant and fertile, and furnishes the town with a good agricultural trade. There are also whisky-distilleries. Ballinacurra, 1½ m. south on the estuary, serves as a small port. The grammar school was founded in 1696, and here among its students were John Philip Curran and Isaac Butt. Midleton is governed by an urban district council.

MIDNAPORE, a town and district of British India, in the Burdwan division of Bengal. The town is 68 m. W. of Calcutta; it has a station on the Bengal Nagpur railway. Pop. (1901), 33,440. It is an important centre of trade, the town being of a navigable canal to Calcutta, and also the junction for the Sini branch of the Bengal-Nagpur railway. There are manufactures of brass and copper wire. It has an American mission, a municipal college, and a public library founded in 1852.

The district of Midnapore has an area of 5186 sq. m. The general appearance is that of a large open plain, of which the greater part is under cultivation. In the northern portion the soil is poor, and there is little wood. The country along the western boundary, known as the Jungle Mahals, is undulating and picturesque; it is almost uninhabited. The eastern and south-eastern portions are swampy and richly cultivated. The chief rivers of the district are the Hugli and its three tributaries, the Rupnarayan, the Haldi and the Rasupur. Th Midnapore high-level canal used also for irrigation runs almost due east and west from the town of Midnapore to Ulubaria on the Hugli 16 m. below Calcutta, and affords a continuous navigable channel 53 m. in length. There is also a tidal canal for navigation, 26 m. in length, extending from the Rupnarayan river. The district is traversed as well by the Bengal-Nagpur railway towards Orissa, with a branch to Chota Nagpur. The jungles in the west of the district yield lac, tussur, silk, wax, resin, firewood, charcoal, &c., and give shelter to large and small game. The principal exports are rice, silk and sugar; and the chief imports consist of cotton cloth and twist. Salt, indigo, silk, mats and brass and copper utensils are manufactured. Both silk and indigo are decaying industries. The population in 1901 was 2,760,114, showing an increase of 6% in the decade.

The early history of Midnapore centres round the ancient town of Tamluk, which in the beginning of the 5th century was an important Buddhist settlement and maritime harbour. The first connexion of the English with the district dates from 1760, when Mir Kasim ceded to the East India Company Midnapore, Chittagong, and Burdwan (then estimated for the entire revenue of Bengal) as the price of his elevation to the throne of Bengal on the deposition of Mir Jafar.

MIDRASH, a very common term in Jewish writings for “exposition” and a certain class of expository literature. The word also occurs twice in the Old Testament (1 Chron. xii. 22, xx. 33, R. V. Midrash; and xiii. 34, R. V. Midrashim), but in these passages the term means “(to search out, enquire)” and denotes some explanation or exposition, which, in contrast to the more literal exegesis (technically called pesah “simple”), endeavours to reach the spirit lying below the text. It may be defined as a didactic or homiletic development of some thought or theme, characterized by a more subjective, imaginative and ampliative treatment. Jewish Midrash falls broadly into two classes: Halaka (q.v.) or Halakah (walking, way, conduct) and Haggadah (narrative with a purpose, homily; Aramaic equivalent Aqgadah; the incorrect form Agadah rest upon a mistaken etymology). The former dealt with legal and ritual matters; it flourished in the schools and developed into the most subtle casuistry. The latter covered all non-halakic exposition and was essentially popular. It embraced historical and other traditions; stories, legends, parables and allegories; beliefs, customs and all that may be known in the folk-lore. It was dependent on the narrative, the prophetic and the poetical writings of the Old Testament, and it had a more spiritual and ethical tone than the Halaka. In both classes, accepted tradition (written or oral) was reinterpreted in order to justify or to deduce new teaching (in its widest sense), to connect the present with a hallowed past, and to be a guide for the future; and the prevalence of this process, the innumerable different examples of its working, and the particular application of the term Midrash to an important section of Rabbinical literature complicates both the study of the subject and any attempt to treat it concisely. Apart from the popular paraphrastic translations of the Old Testament (see Targum), the great mass of orthodox Rabbinical literature consists of (1) the independent Midrashim, and (2) the Mishna which, with its supplement the Gemara, constitutes the Talmud. Both contain Halaka and Haggada, although the Mishna itself is essentially Halakah. The Midrashim are more especially Haggadic; and consequently further information bearing upon Midrash must be sought in the art. Talmud. These two articles

MIDRASH

2. Narrative Midrash.—Of the three different kinds of historical writing—the genetic or scientific, the purely narrative and the pragmatic—it is the last which has prevailed among religious historians. It is extremely difficult to avoid the subjective element in dealing with matters of fact, and the religious treatment of history is influenced, however unconsciously, by the mental environment of the writers. In giving greater prominence to events of religious importance and to their bearing upon the spiritual needs of contemporaries they view and interpret the past in a particular light, and will see in the past those growths which only in their own time have become mature. A latent significance is found, a particular connexion is traced, and a continuity is established, the true nature of which must be tested by critical students. Now, it is subjective history which we find in the earliest references to Midrash. The Midrash of the prophet Iddo (2 Chron. xiii. 22) like the Visions and the Histories of Idde and Shemaiah (ix. 29, xii. 15) which are quoted for the lives of Solomon, Abijah and Jeroboam, are evidently quite distinct from the sources cited in the parallel portions of the earlier collections and the entire spirit of the narratives is different. Similarly, there is a conspicuous difference of treatment of the life of Joash in 2 Kings xi. seq., compared with 2 Chron. xxiii. seq., which refers to some Midrash of the Book of the Kings (xxiv. 27). Although it is uncertain whether this comprehensive Midrash also included the "books of the Kings" (xvi. 11, xxvii. 7 &c.), and the Midrash of Iddo and other related works, it is clear that the Book of Chronicles (q.v.) marks a very noteworthy advance upon the records in the (canonical) Book of Kings (q.v.). It is now recognized that the compiler of the former has used many novel narratives of a particular edifying and didactic stamp, and scholars are practically unanimous that these are subsequent to the age of the Israelite monarchy and present a picture of historical and religious conditions which to judge from earlier sources is untrustworthy. At the same time various details (as comparison with the Book of Kings shows) are relatively old and, on a pri- or grounds, it is extremely unlikely that the unhistorical elements are necessarily due to deliberate imagination or perversion rather than to the development of earlier traditions. The religious significance of the past is dominant, and the past is idealized from a later standpoint; and whether the narratives in Chronicles are expressly stiterd Midrash or not, they are the fruit of an age which sought to inculcate explicitly those lessons which it conceived, were implied in the events of the past. The value of the book lay not in history for its own sake, but in its direct application to present needs. But the tendency to reshape history for the edification of later generations was no novelty when Chronicles was first compiled (about 4th cent. B.C.). Pragmatic historiography is exemplified in the earliest continuous sources (viz. of the "Deuteronomic" writers, i.e. allied to Deut., especially the secondary portions); and there are many relatively early narratives in which the details have been modified, and the heroes of the past are the mouthpiece for the thought of a later writer or of his age. Numerous instructive examples of the active tendency to develop tradition may be observed in the relationship between Genesis and the "Book of Jubilees," or in the embellishments of Old Testament history in the Antiquities of Josephus, or in the widening gaps in the diverse traditions of the famous figures of the Old Testament (Adam, Noah, Enoch, Abraham, Moses, Isaiah, Ezra, &c.), as they appear in non-canonical writings. In such cases as these one can readily perceive the different forms which the same material elements have assumed, and one may distinguish the unadulterated narratives which are clearly later and secondary. Accordingly, when there are narratives which cannot be tested in this manner, should they show all the internal marks of didactic expansion and date more than a century later than the text with which they deal, their immediate value will not necessarily lie in the details which appear to be of historical interest, but in their contribution to later forms of tradition and phases of thought. So far then, Midrash tends to include moralizing history, whether we call it narrative or romance, attached to names and events, and it is obviously exemplified wherever there are unmistakable signs of untrustworthy amplification and of some explicit religious or ethical aim colouring the narrative. This, however, is only one of the aspects which have to be taken into consideration when one advances to the Rabbinical Midrash.

3. Continuity of Literature and Material.—Amid obscure vicissitudes in the 7th to 5th centuries, B.C., the canonical books of the Old Testament gradually began to assume their present shape (see PALESTINE: HISTORY). The internal peculiarities show that the compilations are the much edited remains of a larger body of literature, and it may reasonably be supposed that the older sources did not at once perish. There is literary critical evidence for late insertions by exilic or later compilers; the compiler of Chronicles apparently refers to accessible works; and there is a close material relationship between the Old Testament and later literature. All this suggests that Old Hebrew writings, apart from those preserved in the Canon, persisted to a relatively late period. No a priori distinction can be made and no precise chronological line can be drawn between the books of the Canon (Canticles, Ecclesiastes, Esther, Ezekiel and Proverbs) had been at one time or another subjects of debate among the Rabbis) and the Apocrypha (Ecclesiasticus, Judith, Maccabees and Tobit, were "allowed"); and the intimate relation between them appears in the character of the "Wisdom Literature" (e.g. Proverbs, and the Wisdom of Solomon), in the treatment of the stories of Esther and Daniel (the history of Susanna), and also in the twofold recensions Ezra and 1 Esdras. Historical or narrative Midrash is exemplified in the "canonical" books Daniel, Esther, Jonah and Ruth, and in the "apocryphal" stories of Daniel (viz. Susanna, where the point lies in the name Daniel = "God is judge"), Esther, Judith, Tobit (and the Ahiger cycle of stories), the story of Zerubbabel (1 Esd. iii. seq., the sequel of which belongs to the canonical Ezra), and the martyrdom of Eleazar (2 Macc. vi. seq., compare 4 Macc.). This is not the place to notice the course of Jewish literary activity in Palestine or Alexandria, whether along the more rigid lines of Pharisaic legalism (the development of the canonical "priestly and," or the popular and less scholastic phases, which recall the earlier apocalyptic tendencies of the Old Testament and were cultivated alike by early Jewish and Christian writers. But after the fall of Jerusalem, partly through the need for systematizing the traditional post-biblical Jewish and partly through disputes with the Christians, orthodox Rabbinism received the stamp which has since characterized it. The traditional or oral law was codified in the Mishna (see TALMUD, § i, seq.), the Canon was

1 E.g. Judg. i. (see G. F. Moore, Encyc. Bib. "Historical Lit.," col. 2685, middle), 2 Sam. ix.-xx., &c.
fixed, and the fluctuations in the MSS. of the Old Testament (which, like the numerous variations in the Septuagint, complicated exact exegesis) gave way to what was virtually a single text.

Moreover, the important body of apocryphal and pseudopigraphical literature, with all its links between Christianity and Judaism, fell into disfavour on both sides. This literature is especially valuable because it illustrates contemporary Halakha and Haggada, and it illuminates the circle of thought with which Jesus and his followers were familiar; it thus fills the gap between the Old Testament and the authoritative Rabbinical Midrash which, though often in a form several centuries later, not rarely preserve older material.

A few miscellaneous examples of related Midrashic details may be cited:

i. The book of Jubilees (a aggadic and halakic Midrash on Genesis, about 2nd century B.C.), contains the story of the war between Amorite Kings and Jacob (ch. xxiv.). This is known to the probably contemporary Testament of Judah and to much later Midrashic literature. According to Jubilees (ch. v.), and also then in the apocryphal “book of Jashar”, and is evidently connected with the cryptic allusion to the capture of Shechem in Gen. xlviii. 22 (R. V. marg.), unless we suppose that the latter was suddenly expanded into a full-fledged account on the occasion. It may be that an old extra-canonical tradition (for which a case can be made) continued to survive the compilation of Genesis (q.v.) and ultimately assumed the various exaggerated forms now extant. Naturally the process of tradition would work in the other direction as well. But it is still possible to be preserved in Gen. loc. cit.—does not prejudice the problem of its origin or accuracy: in Jub. the story is useless for Jacob’s history, and is probably influenced by a recollection of more recent events in the Talmudic tradition.

ii. A curious account of war between Egypt and Canaan after Joseph’s death recurs in Jub. xiii., Test. of Simeon, viii., and Benjamini vii., and is connected with details (burial of Jacob’s sons at Hebron) recorded in the Talmud, ch. xxv. 6. A correspondence is also, in part, between the stories wherein Moses leads the Egyptians against Ethiopia (Ant. ii. 10, for parallels see Moore, Ency. Bib. col. 208 sq.), and this is found in the late chronicles of Jerome and the Book of Jashar (cf. cf. Ap. Prob. p. 212). The story in Ex. xi. 1, 25, with the former may be linked with Gen. l. 9 (where the course of chariots and horsemen would invite speculation). But the latter with the Cushite wife of Moses; but although one may grant that the account of the Talmud is not necessarily preserved all the old traditions, the contents of the latter cannot be recovered from the later persisting Midrash.

iii. The allusion in Jude 9, to the contention of the archangel Michael for the throne of Moses belongs to a group of traditions which have been collected by R. H. Charles (Assumption of Moses, pp. 105 seq.), and it appears that the incident was familiar to Clement of Alexandria, Origen and other early writers. Moreover, Jude 16, alludes to the story of Moses in Numbers, which has other parallels in Matt. xxv. 29; Acts xvii. 36, 38 seq. (ibid. pp. lix. seq.). Here may be added Jannes and Jambres, who stood against Moses (2Tim. iii. 8); these or related names were known in Egypt in the 1st century B.C. (with Irenaeus, c. 200 A.D.); Origen (who refers to a book of Jannes and Jambres), and various earlier and later Jewish sources; see I. Abrahams, Ency. Bib. col. 2327 seq.; H. St. J. Thackeray, Relation of St Paul to contemporary Mythology (2nd ed., p. 126). Jewish traditions of Abraham in Ur of the Chaldees recur in the Targums, Midrashic works, and earlier in the book of Jubilees (ch. xli., ed. Charles, p. 91; cf. also Judith vi. 6 seq.). The legends of his escape from a fiery furnace may have a philological origin (interpretation of “fire”), but the allusion to the redemption of Abraham in Is. xxii seems to indicate that older tradition was fuller than the present records in Genesis, and supplies another example of the link between Jewish and Midrashic traditions.

v. Not to multiply examples further, it may suffice to refer to (a) the apparent belief that the serpent tempted Eve to unchastity (2Cor. xi. 3 seq., see Thackeray pp. 50 seq.); (b) the descent of the angels upon earth (Gen. vi. 1 seq.; Jude xii. 14 seq., see Charles, Jubs. p. 367 seq.; Chaubet, H. M., Parallels, State of the Pal. Explo. Fund., 1903, pp. 233 seq., and the Midr. Abkhr, see Jer. Ezech. viii. 572); (c) the relationship between the Midrashic developments of the story of Esther in Josephus, the Greek and Old Latin Versions, the Talmud, and midrash with B. F. Law's Haggadah, Esther, pp. 20, 100 and passim); and (d) the numerous minor miscellaneous parallels noticed in recent annotated editions of the

---

2 Note also the allusion to this writer in W. J. T. v. 22, upon which contemporary writings are pretty well informed.

4 Midrashic Exposition.—The Talmud poetically describes Midrash as a hammer which wakens to shining light the sparks which slumber in the rock; and the simile is a happy one when one considers the interpretative components, the workmen and their workmanship. For the expository and interpretative Midrash was bound up with rules and methods which often appear crude and arbitrary, they are nevertheless those of the age and they helped to build up lasting monuments. It was believed that the Written Word had an infinite fulness; according to the Midr. Bemidbar Rabba every word of the Law had seventy different aspects, and Philo of Alexandria held that there are no superfluous words in Scripture. Consequently an exaggerated emphasis is often laid upon single words; as, for example, in the school of Rabbi Akiba, where even individual letters were forced to reveal their meaning. Thus, since the Hebrew ""eth", which marks the accusative, is also the preposition “with”, Deut. x. 20 (‘thou shalt fear [eth] Yahweh thy God’) was interpreted to include the veneration of the doctors of the law along with Yahweh. Many have complained of literal interpretation can of course be found, but arbitrary cases, it is perhaps safe to be more cautious to an obviously far-fetched interpretation or to the endeavours to find some authoritative support for teaching which it was desired to inculcate. Thus faulty proof rather than faulty inference is illustrated when the word “in-number” (Ex. xii. 4) was used to confirm the Halakha that the man who killed the Passover lamb must know how many people were about to share it (Jew. Ency. viii. 570). Often the biblical text cannot be used to supply more than a hint or a suggestion, and the particular application in Halakha or Haggada must be taken on its merits, and the teaching does not necessarily fall because the exegesis is illegitimate. To take another specimen the Mešiklo on Ex. xx. 25 infers from the unusual form of the word “it”, that the prohibition of the iron applies only to it, i.e. the altar, and not to stones used in building the temple. This Halakha is followed by a haggadic explanation of the prohibition: “iron abridges life while the altar prolongs it; iron causes destruction and misery, while the altar produces reconciliation between God and man; and therefore the use of iron cannot be allowed in making the altar.” Such were the sparks that could be hammered out of the rock, and it is instructive to observe similar exegetical methods in the New Testament. Exegesis upon a single word is illustrated by Gal. iii. 16, where the argument rests upon the word “seed” (and not the plural “seeds”) in the proof-text, and the same word in Rabbinic writings is used to support other arguments. By identical kinds of reasonings in Lev. xix. 14 (not to put a stumbling block before the blind) is the ground for cautioning a father against striking an adult child, and Deut. xxv. 4 (the law of the muzzled ox) is used to show that God’s labourer is worthy of his hire. Again, since through Eve sin entered into the world, woman must be subordinate to man (1Tim. ii. 11-15), or she who has extinguished the fire of the lampstone by lighting the festal candles on the sabbath (Talm. Shabb. 55). By the allegorical method Is. ix. 13 is interpreted as applying to Jesus (Luke iv. 16-22), and frequently passages which originally had another application have a Messianic reference in...

MIDRASH

Christian and Rabbinical teaching. Similarly the application of Hos. ii. 23, not to the scattered tribes of Israel, but to the Gospel of Christ, is reminiscent of the Mishna and to Romans ix. 25 seq. (Sandy and Headlam, Comment. ad loc.) The Apostles Paul, once a disciple of the famous Rabbi Gamaliel, uses in 1 Cor. x. 4 ("the spiritual rock that followed them") a familiar Jewish Haggada which, however, he interprets, even as, when he identifies the "rock" with Christ, he diverges from the Alexandrian Philo who had identified it with Wisdom or the Word of God. Moreover, not only are passages thus taken out of their context, but they are combined, especially when they contain the same words or phrases, or appear to have the same or similar thoughts or aims. The Talmud, with a reference to Prov. xxxi. 14 ("she bringeth her food from afar"), says "the words of the Torah are poor (or deficient) in one place but rich in another." Hence in the Mid. Siphre on Numbers xv. 39, "ye shall not seek after... your own eyes" is explained to refer to adultery, after the words of Samson "she is pleasing in my eyes" (Judg. xiv. 3); and on Deut. vi. 5 it charges man to love the Lord "with all thy soul... even if he take away thy soul," the teaching being based upon Ps. xlv. 22.1 Similarly, in the New Testament, after the same method, Mal. iii. 1 and Is. xl. 3 (linked by the phrase "to prepare the way") are combined in Mark i. 2 seq.; Abraham's faith (Gen. xv. 6) and temptation (xix. 1) are associated in James ii. 21-23, as also in contemporary Jewish thought; and by other combined quotations Paul enunciates the universality of sin (Rom. iii. 10 seq.) and the doctrine that Christians are God's temple (2 Cor. vi. 16 seq.). Proceeding upon such lines as these, the Jews wove together their Midrashic homilies or sermons where, though we may find much that seems commonplace, there are illuminating parables and proverbs, metaphors and similes, the whole affording admirable examples of the contemporary thought and culture, both of the writers and—what is often overlooked—the level of their hearers or readers. Like many less ancient discourses, the Midrashim are apt to suffer when read in cold print, and they are sometimes judged from a standpoint which would be prejudicial to the Old Testament itself. But they are to be judged as Oriental literature and if they contain jarring extravagances and puerilities, one may recall that even in modern Palestine it was found that the natives understood Robinson Crusoee as a religious book more readily than the Pilgrim's Progress (J. Robertson, Early Rel. of Israel, 1892, p. 66). In making allowance for the defects (without which they would probably not have appealed to the age) it must be remembered that some of the Rabbis themselves recognized that the Midrashic Haggada was not always estimable.

An interesting example of combined quotation is illustrated in Matt. xii. 4-8, where the teaching of Jesus on the law of the Sabbath rests upon 1 Sam. xvi. 1-6, Num. xxviii. 9 seq. and Hos. vi. 6. Apopron of this law the Rabbinical arguments are worth noting. Apparently the severe rules laid down in Jubilees 1.8-12 (see R. H. Charles, ad loc.) were exceptional. It was assumed that the Sabbath need not be rigorously observed if justified by Exod. xx. 12. Also, where the singular use of the restrictive particle ak (silver?) supported the teaching that other Sabbaths need not be observed. Also, from the words "holy unto you" (v. 14) it was taught that "the holy, but not the holy unto you," are to be observed. The Sabbath, therefore, is distinguished from other Sabbaths, and hence the phrase "almost the Sabbath," which is used for the Sabbath, and not for the "Sabbath," is often explained by "the Sabbath which you are not given to the Sabbath." Hence the Sabbath might be broken when life was in danger. Moreover, it was argued that a battle need not be stopped from religious considerations, e.g. the Sabbath. This is in agreement with what the Passover Lambs could be sacrificed on the Sabbath, and justification for this was found in Num. ix. 2 "in its season" (Pesah 66a). See further on this subject, and on the evasions of the Sabbath law, in R. H. Charles, Subs. in Judaea, pp. 297 sq.; ibid. in C. G. Montefiore, Hist. of the Jews, i. 259 seq. (for ibid. Hastings, Dict. Bibl. v. 63, and also R. Driver, Hastings' Dict. iv. 320 seq. With the above interpretations, cf. A. H. McNeil on Matt. xii. 5. John vii. 23; the "apriori element in them perhaps suggests that [these] arguments were kept out of sight later in Pharisaic teaching, and who had realized the inadequacy of the law" (Swete's Camb. Bibl. Essays, 1909, p. 226). For other examples illustrating Rabbinical method of exegesis in the New Testament, see McNeil, pp. 221 seq. ("Our Lord's use of the Old Testament"); R. Driver, op. cit. 436 seq., and Thackray, op. cit. (ch. vii. "use of the Old Testament", ch. viii. "St Paul the Haggadist"). The latter observes (p. 203): "the arguments by which Paul tried to convince his opponents of the true meaning of the Old Testament as pointing forward to the New, are those which they themselves have employed for another purpose; and to some extent we need not doubt that they were selected for that very reason. They were the arguments which were best calculated to appeal to them. Quite in accordance with this, there is a system of question and answer (Rom. x. 5 seq., 16 seq.), and the argument in the sequence: statement, objection and reply, appears already in the book of Malachi (q.v.).

5. The Jewish Midrashim.—The earlier stages in the growth of the extant Rabbinical Midrashim cannot be traced with any certainty. Although there are several allusions to early written paraphrases, notably those of R. Akiva, we are as yet unable to trace a system of paraphrasing back to the time of the Mishnah and Tosephta (Talmud, § v), while in the halakic Midrashim (where the decisions are given in connection with the biblical passage from which they were derived) they follow the sequence of the text of the Old Testament. The Haggada was likewise collected according to the traditional order of the Old Testament. But the homiletic discourses of the homiletic Midrashim are classified according to the reading of the Pentateuch in the Synagogue, either the three weekly cycle, or else according to the sections of the Pentateuch and Prophetic books assigned to special and ordinary Sabbaths and festivals. Hence the latter are sometimes styled Peirūshi ("section"). The homiletic Midrashim are characterized by (a) a poem, an introduction based upon some biblical text (not from the lesson itself), which led up to (b) the exposition of the lesson, the first verse of which is more fully discussed than the rest. They conclude (c) with Messianic or consolatory passages on the future glory of Israel. A feature of some Midrashim (e.g. nos. 4, 5d, e, and 7 below) is the halakic exordium which precedes the poems.2

Among the more important Midrashim are: i.—Mihbālā (Aram. "measure," i.e. "rule") best known as the name of a now imperfect halakic Midrash on Exod. xii.—xxiii. 19 (also xxxi. 12-17 and xxxv. 1-3). It represents the school of R. Rabbi Ishmael, is a useful source for Old Haggada (especially on the narrative of Exodus), and is interesting for its variant readings of the Canonical Masoretic text.4 Edited by Blasius Ugelino, Thes. Antiq. Sacr. xiv. (Venice, 1744, with a poor Latin translation), more recently by J. H. Weiss (Vienna, 1865) and M. Friedmann (ibid. 1879). German trans. by J. Winter and A. Wünsche Leipzig, 1909. See further J. Z. Lauterbach, Jev. Ency. v. 444 seq.

ii. Siḥrē (Aram. "the book") or Toraḥ Kōḥēmā ("the law of the priests"). (Swete, use of the "priests"), a commentary on Leviticus, mainly halakic, the text being a source for various maxims. (On Lev. xix. 17 seq., neighbourly love and abstinence from vengeance constitute, according to R. Aqiba, the great principle of the Torah.) It is one of the best for the interpretation to the Pentateuch and Tōḥōrāh. Latin trans. in Ugelino, vol. xiv.; recent editions by I. H. Weiss (Vienna, 1862), and with the commentary of Shimmon (Shamon) of Siens (Warsaw, 1866); see Jev. Ency. xli. 330 seq. ("Aram. books"); an old composite collection of Halakha on Numbers, after R. Ishmael's school; and on Deut. after that of R. Aqiba, although the haggadic portions belong to the former. Latin in Ugel. xv.; recent edition, with good introduction by acad. Viennae (Venetia), 1691; see Jev. Ency. xi. 332 seq.

The above works, although of 5th century or later date in their present form, contain much older material, which was perhaps first redacted in the earlier part of the 2nd century, A.D. They are of

1 Cited by S. Schechter, Hastings' Dict. Bibl. v. 64.
2 See, on this point, Jev. Ency. viii. 549 seq., 552, 576; Schechter, op. cit. 63 seq. For col. 355 seq., the system of objection and answer (Rom. x. 5 seq., 16 seq.).
3 See more fully Jev. Ency. xlii. 553. Cf. for the structure, the hopeful concluding notes in the prophecies (e.g. Amos) and the discourse after the reading of the lesson from the prophets in Luke iv. 17 seq., Acts xiii. 15 seq.

Представителями огнестрельного оружия в Бабилонии были:

iv. Tanhumā, один из старейших на все принадлежит к Пентатеуку, с известными проницательными его иудаистами и protestantами. Это сочинение, составленное в 1880-1885, было опубликовано в 1892-1893. Этот труд, с транслюциями, оказал большое влияние на изучение Пентатеука.

v. Midrash Rabbah (или Rabbata), большая коллекция из неразделенных и датированной, прежде чем она была написана на 1880-1885. Это сочинение, составленное в 1880-1885, было опубликовано в 1892-1893. Этот труд, с транслюциями, оказал большое влияние на изучение Пентатеука.

vi. Petišq (другое) — P. de-Rak-Kahan, содержит 33 или 34 предложений в разделе, посвященном обряду Пасхи. В этом разделе содержится речь Р. Abba Bar Kahan, который был уважаемым преемником B. Abba Bar Kahan. Хотя он не был уважаемым преемником, его речь была уважаемым преемником R. Abba Bar Kahan.

Tišq (другое) — P. de-Rak-Kahan, содержит 33 или 34 предложений в разделе, посвященном обряду Пасхи. В этом разделе содержится речь Р. Abba Bar Kahan, который был уважаемым преемником B. Abba Bar Kahan. Хотя он не был уважаемым преемником, его речь была уважаемым преемником R. Abba Bar Kahan.
preliminary schools and has been appointed to a ship. The French equivalent is aspirant, and other European navies use that name, or cadet.

MIDSOMER NORTON, an urban district in the northern parliamentary division of Somersetshire, England, 12½ m. S.S.W. of Bath, on the Somerset & Dorset and the Great Western railways. Pop. (1901), 5,809. The town is pleasantly situated in a billy district, between two branches of the small river Somerset. The church of St John the Baptist, principally Perpendicular, has in its tower three bells presented by Charles II. Both this town and the adjacent urban district of RADSTOCK (pop. 3355) have a considerable trade in coal, which is mined in the vicinity. The coalfield extends northward towards Bristol, and is of great importance to the manufactures of that city.

MIDWIFE (Mid. Eng. midwif, mydwyf or medecwife, from preparation mid, with, and wife, i.e. woman, in the sense of one who is with the mother, or from adjective mid, one who is the means of delivering the mother, a woman who assists other women in childbirth). As a class, midwives were recognized in Egypt in the time of the Jewish captivity. It was the custom in that country for a midwife to attend upon a woman in confinement, as it is to-day in the East, that women should be attended in confinement only by those of their own sex. From that period more attention was given to the practice of midwifery by the medical profession (see OBSTetrics), while in continental Europe, towards the close of the 17th century, special schools were instituted for the proper training of midwives. But it was not until well in the 17th century that any supervision or regulation was imposed on those who acted as midwives. Now in practically every European country midwives are under strict state control, they are required to undergo a course of thorough training, and their practice is carefully regulated by legislation.

In France midwives (sages femmes) are divided into a first and a second class. Those qualifying for both classes go through a two years' course of training and examinations. To obtain the right to practice midwifery, as well as in anatomy, physiology and pathology. A midwife of the first class has a superior status and can practise in any part of France, while those of the second class are restricted in their practice to the department for which the certificate was issued. Their qualifications allow them also to vaccinate and to prescribe certain antimicrobial preparations. They are not allowed to use instruments and must call in a medical man in those cases which require medical intervention. They are not allowed to call a child to a hospital. In Spain midwives are allowed to practise on the result of an examination after studies covering at least four half-years. The diploma is issued by the director-general of public instruction. In Germany the midwives are required to pass an examination in the state. They can conduct confinements independently and without the aid of medical man. They must be provided with a certificate from the police authorities, and must reside in special districts—called see in Italy. According to the law, the training and pay of midwives are under the charge of the medical department of the ministry of the interior. In each town of a province or region there is stationed one senior midwife and a number of junior midwives in proportion to the number of districts in the province. The examination for the issue of certificate of competency is carried out by the Medico-Chirurgical Academy and certain of the universities. A duly-licensed midwife, on presentation of her licence, is at once excluded from the tax-paying class, and is entitled to the free use of public baths. The general code of Russian laws lays down extensive rules for the carrying out of the duties of midwives. In Norway all midwives are licensed after examination and are under the control and inspection of the board of health. Payment is made for informed and unaided midwives. A tax is usually paid by the parish, but also receive fees according to the means of the person attended. In Sweden a certificate of competency and of having passed an examination does not give a midwife a right to practise until a note has been made on the certificate that the oath of office has been duly taken. All midwives are under the control of the board of health. When a midwife takes up residence in a parish, or moves from one place to another, she must announce the fact within a month to the nearest appointed doctor and exhibit her certificate. In towns the midwife is entitled to remain outside her residence; she must not absent herself from home without leaving word as to where she may be found and at what hour she probably return. In the country a midwife may be paid out of the ordinary local rates. In the country a midwife is subject to the same restrictions as in the city, and the practice of midwifery is almost entirely in the hands of women. In Holland a certain number of candidates are given free training by the state in return for their practising in midwifery in the country. Continuous district rates are paid to any of the states of the United States have also passed laws for the registration of midwives.

In England alone there was no regulation of any kind so late as 1920. The person, however ignorant and untrained, could describe herself as a midwife and practise for gain. Several societies made continuous efforts towards the close of the 19th century to obtain legislation. A select committee on midwives' registration reported in 1898 that the evidence they had taken showed that there was at the time "serious and unnecessary loss of life and health and permanent injury to both mother and child in the treatment of childbirth, and that some legislative provision for improvement and regulation is desirable." The Government gave its assistance towards the same plan in 1893. Eventually a bill was drafted with the object of securing the examination and registration of midwives, but, although introduced several times into the House of Commons, it was never passed. The Statutes of 1892 and 1898, which gave to any woman after the 1st of April 1905 to call herself "midwife" without a certificate, or to act as a midwife for gain without a certificate after the 1st of April 1910. Existing midwives (those who had certificates in midwifery from certain recognized institutions, or produced satisfactory evidence at the passing of the Act) were allowed to claim certificates within two years from the 1st of April 1903. The act created a certification board to regulate the names of the midwives and the issue of certificates and the conditions of admission to the roll of midwives; to regulate the course of training and conduct of examinations; to regulate, supervise, and restrict within due limits the practice of midwifery in the state; to remove from the roll the name of any midwife who disobeys the rules and regulations laid down from time to time, to issue and cancel certificates, etc. There is an appeal to the High Court of Justice in respect of the certification of a name, but the appeal must be made within three months. Local authorities are required to exercise supervision over the midwives within their area; they must investigate charges of malpractice, negligence or misconduct; exercise control over the educational and moral training of the midwives; and must supply the central board with the names and addresses of those practising within their area, and notify any death. The local authority must appoint a committee to carry out its powers or duties under the Act. The certificate is not valid until the holder is registered as a local authority, such as a district council. The act provides for penalties for obtaining a certificate by false representation or for willful falsification of the roll. The act does not apply to Ireland or Scotland.

Mieres, a town of northern Spain, in the province of Oviedo, 12 m. by rail S.E. of Oviedo, on the river Caudal, a tributary of the Nalon. Pop. (1900), 18,683. Mieres is the chief town of a mountainous, fertile and well-wooded region in which coal, iron and copper are extensively mined and worked. Sulphur and cinnambar are obtained in small quantities. The town contains large iron foundries and chemical works, and has an active trade in fruit, cider, timber and live stock.

MIEREVELT (MIEREVELD or MIREVELD), Michiel Jansz Van (1567-1641), Dutch painter, was born at Delft, the son of a goldsmith, who apprenticed him to the copperplate engraver J. Wierix. He subsequently became a pupil of Willem Van Heemskerck of Delft, with whom he studied from 1583 to 1587, and with whom he signed his early drawings. He went to Delft, and there received his diploma at the University of Leuven. Devoting himself first to still life, he eventually turned to portrait painting, in which he achieved such success that the many commissions entrusted to him necessitated the employment of numerous assistants, by whom hundreds of portraits were turned out in factory fashion. The works that can with certainty be ascribed to his own hand are for their sincerity, severe drawing and harmonious colour, but comparatively few of the two thousand or more portraits that bear
his name are wholly his own handiwork. He settled down in
his native town, but went frequently to The Hague, where
he entered the guild of St Luke in 1635. So great was his reputa-
tion that he was patronized by royalty and acquired great
wealth. The king of Sweden and the count
palatine of Neuburg presented him with golden chains, Arch-
duke Albrecht gave him a pension, and Charles I. vainly endeav-
oured to induce him to visit the English court. Though
Mierevelt is chiefly known as a portrait painter, he also executed
some mythological pieces of minor importance. Many of
his portraits have been reproduced in line by the leading Dutch
engravers of his time. He died at Delft on the 27th of June
1647.
The Ryks Museum in Amsterdam has the richest collection
of Mierevelt’s works, chief of them being the portraits of William,
Philip William, Maurice, and Frederick Henry of Orange,
and of the count palatine Frederick V. At The Hague Museum
are four portraits of the house of Orange, of Frederick V., king of Bohemia, and of Louise de Coligny as a
widow. Other portraits by him are at nearly all the leading
continental galleries notably at Brunswick (3), Gotha (2),
Schwerin (3), Munich (2), Paris (Louvre, 3), Dresden (4), Berlin
(2), and Darmstadt (3). The town hall of Delft also has
numerous examples of his work.
Many of his pupils and assistants rose to fame. The most
gifted of them were Paulus Moreelse and Jan van Raveryen.
His sons Pieter (1596–1623) and Jan (d. 1633), and his son-in-law
Willem Jacobi Delft, probably painted many of the pictures
which go under his name. His portrait was painted by Van
dyck and engraved by Delft.
Mieris, the name of a family of artists who practised paint-
ing at Leiden for three generations in the 17th and 18th centuries.
1. Frans van Mieris, the elder (? 1635–1681), son of Jan Mieris,
a goldsmith and diamond setter, was born, according to
Houbraenk, at Leiden on the 16th of April 1635, and died there
on the 12th of March 1681. His father wished to train
him to his own business, but Frans preferred drawing to chasing,
and took service with Abraham Torenvliet, a glazier who kept
a school of design. In his father’s shop he became familiar
with the best artist and the dress of people of distinction. His eye
was fascinated in turn by the sheen of jewelry and stained glass;
and, though he soon gave up the teaching of Torenvliet for
that of Gerard Douw and Abraham van den Tempel, he acquired
a manner which had more of the finish of the esquisses of the
Dutch school than of the breadth of the disciplines of Rembrandt.
It should be bore in mind that he seldom chose panels of which
the size exceeded 12 to 15 in., and whenever his name is
attached to a picture above that size we may surely assign
it to his son Willem or to some other imitator. Unlike Gerard
Douw when he first left Rembrandt, or Jan Steen when he
started on an independent career, Mieris never ventured to
design figures as large as life. Characteristic of his art in its
minute proportions is a shiny brightness and metallic polich.
The subjects which he treated best are those in which he liked
to specialize, namely allegories, but he sometimes succeeded in
boring incidents and in portrait, and not infrequently he ventured on allegory. He repeatedly painted the satin skirt which Ter Borch brought into fashion,
and he often rivaled Ter Borch in the faithful rendering of
rich and highly-coloured woven textures. But he remained
below Ter Borch and Metsu, because he had not their delicate
perception of harmony or their charming mellowness of touch
and tint, and he fell behind Gerard Douw, because he was hard
and had not his feeling for effect by concentrated light and
shade. In the form of his composition, which sometimes
represents the framework of a window enlivened with greenery,
and adorned with bas-reliefs within which figures are seen
to the waist, his model is certainly Gerard Douw.
It is a question whether Houbraenk has truly recorded this
master’s birthday. One of his best-known pieces, a party of
ladies and gentlemen at an oyster luncheon, in the Hermitage
at St Petersburg, bears the date of 1650. Celebrated alike
for composition and finish, it would prove that Mieris had reached
his prime at the age of fifteen. Another beautiful example, the
"Doctor Feeling a Lady’s Pulse,” in the gallery of Rubens,
is dated 1656; and Waagen, in one of his critical essays, justly
observes that it is a remarkable production for a youth of
twenty-one. In 1657 Mieris was married at Leiden in the
presence of Jan Potheuken, a painter, and this is the earliest
written record of his existence on which we can implicitly rely.
Of the numerous panels by Mieris, twenty-nine at least are
dated—the latest being an allegory, long in the Ruhl collection
at Cologne, illustrating what he considered the kindred vices
of drinking, smoking and dicing, in the year 1680.
Mieris had numerous and distinguished patrons. He received
valuable commissions from Archduke Leopold, the elector-
palatine, and Cosimo III., grand-duke of Tuscany. His practice
was large and lucrative, but never engendered in him either
carelessness or neglect. If there be a difference between the
painter’s earlier and later work, it is that the former was clearer
and more delicate in flesh, whilst the latter was often darker
and more vivid in the shadows. When he died his clients
naturally went over to his son Willem, who in turn bequeathed
his painting-room to his son Frans. But neither Willem nor
Frans the younger equalled Frans the elder.
2. Willem van Mieris (1662–1747), son of Frans. His
works are extremely numerous, being partly imitations of the
paternal subjects, or mythological episodes, which Frans
habitually avoided. In no case did he come near the excellence
of his sire.
3. Frans van Mieris, the younger (1689–1753), also lived
on the traditions of his grandfather’s studio.
The pictures of all the generations of the Mieris family were
successively imitated by A. D. Snaphaan, who lived at Leipzig
and was patronized by the court of Anhalt-Dessau. To those who
would study his deceptive form of art a visit to the collection
of Wörlitz near Dessau may afford instruction.
Mifflin, Thomas (1744–1800), American soldier and
politician, was born in Philadelphia, Pennsylvania, on the 17th
of January 1744, of Quaker parentage. He graduated at the
college of Philadelphia (now the university of Pennsylvania)
in 1760. As a member of the Pennsylvania house of representa-
tives in 1772–1775, he was an ardent Whig, and in 1774 was a
member of the first Continental Congress. After the outbreak
of the War of Independence he devoted himself chiefly to the
enlisting and drilling of troops, and was chosen major of a
regiment. In June 1775 he entered the continental service
as Washington’s first aide-de-camp, and in August was chosen
quartzer GENERAL. He became a brigadier-general in
May 1776 and a major-general in February 1777. On the 5th
of June 1776 he was succeeded as quartzer-general by
Stephen Moylan. Moylan, however, proved incompetent, and
Mifflin resumed the office on the 1st of October. In the autumn
of 1777 Mifflin was a leader in the obscure movement known as
the Conway Cabal, the object of which was to replace Washing-
ton by General Horatio Gates. On the ground of ill health Mifflin
tendered his resignation on the 8th of October, and on the 1st
of November Congress accepted his resignation as quartzer-Ger-
gen, but continued him in rank as major-general without
pay. On the same day he was appointed a member of the new
board of war, and on the following day was asked to continue
as quartzer-general until his successor should be appointed.
On the 21st of November he urged before the old board of war
and ordinance that Gates should be made president of the new
board of war “from a conviction that his military skill would
suggest reformations in the different departments of the army
essential to good discipline, order and economy, and that his
character and popularity in the army would facilitate the
execution of such reformations when adopted by Congress.”
The attacks on Washington failed, and in March 1778 Mifflin
was finally superseded as quartzer-general by General
Nathanael Greene. In October of the same year he was removed
from the board of war. The sufferings of the troops at Valley
Forge having been charged to his mismangement as quart-
MIGNARD—MIGNON

MIGNARD, PIERRE (1610—1665), called—to distinguish him from his brother Nicholas—Le Romain, French painter, was born at Troyes in 1610, and came of a family of artists. In 1630 he left the studio of Simon Vouet for Italy, where he spent twenty-two years, and made a reputation which brought him a summons to Paris. Successful with his portrait of the king, and in favour with the court, Mignard pitied himself against Le Brun, declined to enter the Academy of which he was the head, and made himself the centre of opposition to its authority. The history of this struggle is most important, because it was identical, as long as it lasted, with that between the old guilds of France and the new body which Colbert, for political reasons, was determined to support. Shut out, in spite of the deserved success of his decorations of the cupola of Val de Grace (1664), from any great share in those public works the control of which was the attribute of the new Academy, Mignard was chiefly active in portraiture. Turenne, Molière, Bossuet, Maintenon (Louvre), La Vallière, Sévigné, Montespan, Descartes (Castle Howard), all the beauties and celebrities of his day, sat to him. His readiness and skill, his happy instinct for grace of arrangement, attuned for want of originality and real power. With the death of Le Brun (1690) the situation changed; Mignard deserted his allies, and succeeded to all the posts held by his opponent. These late honours he did not long enjoy; in 1695 he died whilst about to commence work on the cupola of the Invalides. His best compositions have been engraved by Audran, Edelinck, Masson, Poilly and others.

MIGNARD, JACQUES PAUL (1809—1875), French priest and public official, was born at Sens, Capet, on the 25th of October 1800. He studied theology at Orleans, was ordained priest in 1824 and placed in charge of the parish of Puiseaux, in the diocese of Orleans. In 1833 he went to Paris, and started L'Univers religieux, which afterwards became Louis Veuillot's ultramontane organ. On severing his connexion with the paper three years later, he opened at Petit Montrouge, near Paris, the great publishing house which brought out in rapid succession numerous religious works at popular prices. The best known of these are: Scripturae sacrae cursus completus; and Theologiae cursus (each in 28 vols., 1840—1845); Collection des auteurs sacrés (100 vols., 1846—1848); Encyclopédie théologique (117 vols., 1848—1866); Patrologiae cursus completus, Latin series in 221 vols. (1842—1855; 2nd edition, 1878 seq.); Greek series, first published in Latin (83 vols., 1856—1861); with Greek text and Latin translation (165 vols., 1857—1866). Unfortunately these editions, brought out in great haste and often edited by superfluous scholars, do not come up to the requirements of modern criticism. By far the most noteworthy is the Patrology, which was superintended by the learned Benedictine J. B. Pitra. Its vast scope leaves it still unique and valuable, where other editions of special works do not exist. The indices in 3 vols. are arranged so that one may easily find any reference in the patristic writings. In February 1868 a great fire destroyed the whole of Migne's printing premises, but he established a new house in Paris, which was purchased in 1876 by the publishers Garnier Frères, who still own all the works brought out by Migne. He died in Paris on the 25th of October 1875.

For a more complete account of Migne's life, see the article in the Catholic Encyclopedia (New York, 1906 seq.).

MIGNON, FRANÇOIS AUGUSTE ALEXIS (1796—1884), French historian, was born at Aix in Provence on the 8th of May 1796, and died at Paris on the 24th of March 1884. His father, a Vendean by birth, was an ordinary locksmith, who enthusiastically accepted the principles of the French Revolution and roused in his son the same love for liberal ideas. François had brilliant successes when studying at Avignon in the lyceé where he was afterwards professor (1815); he returned to Aix to study law, and in 1818 was called to the bar, where his eloquence would have ensured his success, but he interrupted the career of an historian. His abilities were shown in an Éloge de Charles VII., which was crowned by the Académie de Nîmes in 1820, and a memoir on Les Institutions de Saint Louis, which in 1821 was crowned by the Académie des Inscriptions et Belles Lettres. He then went to Paris, where he was soon joined by his friend and compatriot, Adolphe Thiers, the future president of the French republic. He was introduced by J. A. Manuel, formerly a member of the Convention, to the Liberal paper, Courrier français, where he became a member of the staff which carried on a fierce pen-and-ink warfare against the Restoration. He acquired his knowledge of the men and intrigues of the Napoleonic epoch from Talleyrand. He wrote a Histoire de la révolution française (1824) in support of the Liberal cause. It was an enlarged sketch, prepared in four months, in which more stress was laid on fundamental theories than on the facts, which are more rigidly linked together than their historical sequence warrants. In 1830 he founded the National with Thiers and Armand Carrel, and signed the journalists' protest against the Ordonnances de juillet, but he refused to accept his share of the spoil after his party had won. He was satisfied with the modest position of director of the archives at the Foreign Office, where he stayed till the revolution of 1848, when he was dismissed, and retired permanently into private life. He had been elected a member of the Académie des Sciences Morales et Politiques, re-established in 1832, and in 1837 made the permanent secretary; he was also elected a member of the Académie Française in 1836, and sought no further honours. He was well known in fashionable circles, where his witty conversation and his pleasant manners made him a favourite. The greater part of his time was, however, given to study and to his academic duties. Eulogies on his deceased fellow-members, the Academy reports on its work and the prizes awarded by it, which it was part of Migne's duty to announce, are highly appreciated by connoisseurs. They were collected in Mignon's Notices et portraits. He worked slowly when in his study, and willingly lingered over research. With the exception of his description of the French Revolution, which was chiefly a political manifesto, all his early works refer to the middle ages—De La féodalité, des institutions de Saint Louis et de l'influence de la législation de ce prince (1822); La Germanie au viii e siècle, sa conversion au christianisme, et son introduction dans la société civile de l'Europe occidentale (1834); Essai sur la formation territoriale et politique de la France depuis la fin du xii e siècle jusqu'à la fin du xii e siècle (1836); all of these are rough sketches showing only the outlines of the subject. His most noted works are devoted to modern history. For a long time he had been taken up with a history of the Reforma­tion, but only one part of it, dealing with the Reforma­tion at Geneva, has been published. His Histoire de Marie Stuart (2 vols., 1851)
MIGNON—MIGRATION

is well worth reading; the author made liberal use of some important unpublished documents, taken for the greater part from the archives of Simancas. He devoted some volumes to the history of Spain, which had a well-deserved success—Charles Quint, son oblivion, son séjour, et sa mort au monastère de Yuste (1845); Antonio Pérez et Philippe II. (1845); and Histoire de la rivalité de François I. et de Charles Quint (1875).

At the same time he had been commissioned to publish the diplomatic acts relating to the War of the Spanish Succession for the Collection des documents inédits; only four volumes of these Négociations were published (1835-1842), and they do not go further than the peace of Nijmegen; but the introduction is conducted, and Mignet reprinted it in his Mélanges historiques.

See the eulogy of Mignet by Victor Duruy, delivered on entering the Académie Française on the 16th of June 1885, and the notice by Jules Simon, read before the Académie des Sciences Morales et Politiques on the 7th of November 1885.

MIGNON, ABRAHAM (1660-1697), Dutch painter, was born at Frankfort. His father, a merchant, placed him under the still-life painter Jacob Merrel, by whom he was taken to Holland about 1660. He then worked under de Heem at Utrecht, where in 1675 he married the daughter of the painter Cornelis Willaerts. Sibyllie Merian (1647-1717), daughter of the engraver Matthew Merian, became his pupil and achieved distinction as a flower painter. He died at Wetzlar. Mignet devoted himself almost exclusively to flowers, fruit, birds and other "still life," though at times he also attempted portraiture. His flower pieces are marked by careful finish and delicate handling. His favourite scheme was to introduce red or white roses in the centre of the canvas and to set the whole group of flowers against a dark background. Nowhere can his work be seen to better advantage than at the Dresden Gallery, which contains fifteen of his paintings, twelve of which are signed. Six of his pictures are at the Louvre, four at the Hermitage, and other examples are to be found at the museums of Amsterdam, the Hague, Rotterdam, Brussels, Munich, Karlsruhe, Brunswick, Cassel, Schwerin, Copenhagen and Turin.

MIGNONETTE, or MIGNONETTE (i.e. "little darling"), the name given to a popular garden flower, the Reseda odorata of botanists, a "fragrant weed," as Cowper calls it, highly esteemed for its delicate but delicious perfume. The mignonette is generally regarded as being of annual duration, and is a plant of diffuse decumbent twiggy habit, scarcely reaching a foot in height, clothed with bluish lanceolate entire or three-lobed leaves, and bearing longish spikes—technically racemes—of rather insignificant flowers at the ends of the numerous branches and branchlets. The plant thus naturally assumes the form of a low dense mass of soft green foliage studded over freely with the racemes of flowers, the latter unobtrusive and likely to be overlooked unless the fragrant fragrance compels attention. It is probably a native of North Africa and was sent to England from Paris in 1742; and ten years later it appears to have been sent from Leiden to Philip Miller at Chelsea. Though originally a slender and rather straggling plant, there are now some improved garden varieties in which the growth is more compact and vigorous, and the inflorescence bolder, though the odour is perhaps less penetrating. The small six-petalled flowers are somewhat curious in structure: the two upper petals are larger, concave, and furnished at the back with a tuft of club-shaped filaments, which gives them the appearance of being deeply incised, while the two lowest petals are much smaller and undivided; the most conspicuous part consists of the anthers, which are numerous and of a brownish red, giving the tone of colour to the inflorescence. In the varieties named Golden Queen and Golden Mauve the anthers have a decided tint of orange-yellow, which imparts a brighter golden hue to the plants when in blossom. A handsome prolific or double-flowered variety has also been obtained, which is a very useful decorative plant, though only to be propagated by cuttings; the double white flowers grow in large massive panicles (proliferous racemes), and are equally fragrant with those of the ordinary forms.

What is called tree mignonette in gardens is due to the skill of the cultivator. Though practically a British annual, as already noted, since it flowers abundantly the first season, and is utterly destroyed by the autumnal frosts, and though recorded as being indigenous to the Netherlands and the Low Countries, it is not a native of these, like many other plants treated in England as annuals, will continue to grow on if kept in a suitable temperature. Moreover, the life of certain plants of this semi-annual character may be prolonged into the second season under glass, and their flowering and setting seed are persistently prevented. In applying these facts to the production of tree mignonette, the gardener grows on the young plants under glass, and prevents their flowering by nipping off the blossoming spikes as soon as they break. The plants then grow and go into seed. These seeds are sown in pots, on a bed of sand, and kept in a cool glasshouse, until the plants are one foot high, when they are set out in the open ground. In this way a very large number can be produced.

For ordinary purposes, however, other plans are adopted. In the open borders of the flower garden mignonette is usually sown in spring, and a great part can be cared for itself; but being a favourite either for window or balcony culture, and on account of its fragrance a welcome inmate of town conservatories, it is also very extensively grown as a pot plant, and for market purposes with this object it is grown in beds in the open ground, and their shooting and the requisite space, since it does not transplant well, and it is thereafter specially grown in pots protected from frosts, and marketed when just arriving at the blooming stage. In this way hundreds of the beautiful pots of blooming mignonette are raised and disposed of every year.

In classifying the odours given off by plants Rimmel ranks the mignonette in the class of which he makes the violet the type; and if we follow the same order we shall be giving it to his class of "lomisoids along with the violet and wallflower.

The genus Reseda contains about fifty species, natives of Europe and West Asia. R. luteola, commonly called dyer's-weed and weld, yields a double yellow yellow with a fine biennial about 2 ft. high, with spikes of whitish flowers.

MIGNONS, LES. In a general sense the French word mignon means "favourite," but the people of Paris used it in a special sense to designate the favourites of Henry III. of France, frivolous and fashionable young men, to whom public malignity attributed dissolute morals. According to the contemporary chronicler Pierre de l'Etoile, they made themselves "exceedingly odious, as much by their foolish and haughty demeanour, as by their effeminate and immodest dress, but above all by the immense gifts the king made to them." The Guises appear to have stirred up the ill will of the Parisians against them. From 1576 the mignons were attacked by popular opinion, and historians accredited without proof the scandalous stories of the time. The best known of the mignons were the dukes of Joyeuse and of Épernon.

MIGNOT, CLAUDINE FRANÇOISE [commonly called MARIE] (c. 1617-1711), French adventuress, was born near Grenoble, at Meylan. At the age of sixteen she attracted the notice of the secretary Pierre des Portes d'Ambлиeurs, treasurer of the province of Dauphiny, and Amblieurs promised to promote his marriage. He married the girl himself, however, and left her his fortune. His will was disputed by his family, and Claudine went to Paris in 1653 to secure her fulfilment. She sought the protection of François de l'Hôpital, marshal of France, then a man of seventy-five. He married her within a week of their first meeting, and after seven years of marriage died leaving her part of his estate. By a third and morganatic marriage in 1672 with John Casimir, ex-king of Poland, a few weeks before his death, she received a third fortune. Immediately on her marriage with Amblieurs she had begun to educate herself, and her wealth and talents assured her a welcome in Paris. She retired in her old age to a Carmelit convent in the city, where she died on the 30th of November 1711. Her history, very much modified, was the subject of a play by Bayard and Paul Dupont, Marie Mignet (1829).

MIGRATION. Under this title will be considered movements of men with intention of changing their residence or domicile. Such migration (Lat. migrare) may be either external—that is, from one country to another, including emigration from another country to colony; or it may be internal—that is, within
the limits of a single country. Under external migration are comprised emigration and immigration, denoting simply direction from and to. The emigrants are at the same time the immigrants; that is, the material of the movement is the same, but the effect upon the country giving up and the country receiving the migrant requires separate treatment. Hence it is proper to separate emigration from immigration. Temporary migration, or travel for purposes of business, enterprise or pleasure, will be considered only incidentally, and because in some cases it is difficult to distinguish between such movements and permanent migration.

Migration in general may be described as a natural function of social development. It has taken place at all times and in the greatest variety of circumstances. It has been tribal, national, class and individual. Its causes have been political, economic, religious, or mere love of adventure. Its causes and results are fundamental for the study of ethnology (formation and mixture of races), of political and social history (formation of states and survival of institutions), and of political economy (mobility of labour and utilization of productive forces). Under the form of conquest it makes the grand epochs in history (e.g. the fall of the Roman Empire); under the form of colonization it has transformed the world (e.g. the settlement of America); under free initiative it is the most powerful factor in social adjustment (e.g. the growth of urban population). It must suffice here to indicate the character of the principal movements in the past, and then describe certain aspects of modern migration. The early movements may be grouped as follows: (a) Prehistoric migrations. Among savage and nomadic nations the whole tribe often moves into new territory, either occupying it for the first time or exterminating or driving out the indigenous inhabitants. We have only vague knowledge of these early movements, laboriously gleaned from archaeology, anthropology and philology. The cause has been commonly said to be the pressure of population on the food-supply. A more probable explanation is the love of booty and the desire of the stronger to take possession of the lands of the weaker. (b) Greek and Roman colonization. Both of these ancient civilizations extended their influence through migration of individual families and the planting of colonies. The motive seems to have been primarily commercial—that is, the love of gain. It may have been partly a sort of "swarming" process, caused by pressure of population at home. In some cases it had a political motive, as the planting of military colonies or providing new homes for the proletariat. The consequences were of course momentous. (c) The German Conquest. Beginning about the 5th century, the Roman empire was overthrown by German tribes from the north of the river Danube and east of the river Rhine. This Völkerwanderung, as it is called by German historians, again transformed the face of Europe, resulting in the establishment of independent kingdoms and a great mixture of races and institutions. It was coincident with the building-out of the feudal system. The conquered in many cases could be left as serfs and tillers of the soil, while the conquerors seized the higher positions of administration and power. (d) The later middle ages saw many minor migratory movements, such as those accompanying the crusades, the pushing of German colonization among the Slavs, and the introduction of Flemish weavers into England. The religious reformation caused a considerable amount of emigration, culminating in the expulsion of the Huguenots from France. (e) The period of discovery and colonisation opened up a new era for migration. The first expeditions were for adventure and booty, especially the discovery of gold and silver. Then came the establishment of commercial posts or factories for the purposes of trade. Finally came colonization proper—that is, the settlement of new countries by Europeans intending to remain there permanently, but still retaining their connexion with the mother country. The migration opening of the world to commerce and the extension of European civilization to vast areas formerly peopled by savages or half-civilized peoples. It meant a great outlet for the spirit of enterprise and adventure, relief from over-population, an enormous increase in wealth and power, and a struggle for supremacy among the nations of Europe. Colonization and colonial policy excited immense attention in Europe; and this extended into the 19th century (e.g. E. G. Wakefield's plans for colonization, and the various colonization societies of modern times). The colonial policy proper was broken down by the revolt of the North American colonies from Great Britain, and later of Mexico and Central and South America from Spain. (f) The movement of population, however, has continued under the form of emigration. This movement is characterized firstly by its magnitude; secondly, by the fact that the emigrant changes his political allegiance, for by far the greater part of modern emigration is to independent countries, and even where it is to colonies the colonies are largely self-governing and self-regarding; and thirdly, it is a movement of individuals seeking their own good, without state direction or aid. This is the 20th century emigration, differing from all preceding forms and having an importance of its own.

Statistics of Emigration.—The direction of the modern movement is from Europe to America, Australia and South Africa, as shown in the following table:

1 The figures relate only to the emigrants of each nationality emigrating from their own country to countries outside of Europe.

2 Exclusive of emigrants to Spanish colonies.

3 Russian emigrants from German ports.
Since 1820 over twenty million persons have emigrated from Europe to countries beyond the sea. The greater part of this emigration has been to the United States of North America. The history of emigration is well shown in the following table of emigration from Great Britain and Ireland. Down to 1853 the figures include all emigrants from British ports; after 1853 emigrants of British and Irish origin only.

</tbody>
</table>

Total | 2,116,501

Prior to 1820 there was no official record of immigration, but it is estimated that the total number of immigrants from the close of the Revolutionary War was 250,000. During the decade from 1820 to 1830 the movement was very moderate. From 1830 to 1840 it steadily increased, but never reached 100,000 per annum. In 1846 came the Irish potato famine, and an enormous emigration began, followed by a very large German emigration from similar causes. The Civil War of the United States interrupted the movement, but it was specially resumed on an enlarged scale owing especially to the improved means of ocean transportation. It culminated in the decade 1880-1890, and declined after the commercial crisis of 1893. Later there was another increase.

The relative movement of nationalities is best presented by the statistics of the United States. The nationality (country of origin) of immigrants coming to the United States, 1871-1895 is shown in the following table:

<table>

A very important transformation has taken place in the proportionate number coming from different countries during the latter half of the 19th century. At first the French and Germans were most prominent. Of later years, the Italians, Czechs, Hungarians and Russians were, as will be seen from the following table, numerously represented.

### Nationality of Immigrants to the United States, 1901–1905.

Total | 100 |

Sex and Age.—Of all the immigrants (1871-1895), 62-25% were males and 37-75% were females.

### Balance of Emigration and Immigration.—Even in the case of immigration from Europe to countries beyond the seas there is some return movement. Emigrants who have been successful in business return in order to end their days in the old country. Those who have not succeeded return in order to be cared for by friends and relatives, or simply from homesickness. Thus, for Great Britain and Ireland, while the emigration of persons of British and Irish origin was, in 1905, 262,077, the immigration of persons of the same category was 272,173, leaving a net emigration of only 199,364. In the United States' statistics we cannot distinguish in the outgoing passenger movement emigrants from other persons. But if for a period of years we take the total inward passenger movement and subtract the total outward movement, we arrive at the net immigration. By this method we arrive at the conclusion that while the gross immigration during the five years 1901-1905 was 3,333,076, the net immigration was only 1,779,976, showing an outward movement of 273,134, or about 7.12% of the total number of immigrants.

### Temporary Emigration.—In many European countries there is not only emigration beyond seas, but a very considerable movement to neighboring countries in search of work, and generally with the intention of returning. Thus in Italy, the permanent emigration (i.e. to countries beyond seas) numbered, in 1905, 447,083; the temporary emigration to European or Mediterranean countries amounted 270,248. This temporary emigration is strongest in the spring, and consists principally of adult males (agriculturists, farmers, and laborers, bricklayers and masons) in search of work. It resembles somewhat the movement of Irish labourers into Great Britain at harvest time. It is notorious that the Italians who emigrate to the United States largely return.

### Effects of Emigration.—There are two views with regard to emigration: one unfavourable, viz., that it is a drain on population, reducing its economic strength and disturbing social and political relations; the second looking upon it as a relief from over-population and a congested labour market. As a matter of fact, emigration has not succeeded in diminishing the population of Europe, which, on the contrary, doubled during the 19th century. The one great exception is Ireland, where population declined from 8,175,124 in 1841 to 4,458,745 in 1901. From 1851 to 1901 the total emigration from Ireland was 3,881,246 or 72.5% of the average population. Emigration, by carrying off the young men and women, also reduces the Irish marriage and birth-rates, which were almost the lowest in Europe. But hitherto the countries of strongest emigration (England, Germany, &c.) have shown practically undiminished birth and marriage-rates and a steady growth in population.

### Intensity of Emigration is measured by the absolute number of emigrants, but by the number of emigrants to the total population. Its effect is shown by comparing the number of emigrants with the excess of births over deaths per thousand of the population. This is shown in the following table (1895):
<table>
<thead>

It will be observed, with the exception of Ireland and Italy, wherever there is a heavy emigration there is usually a considerable excess of births over deaths, i.e., natural increase more than makes up for the loss by emigration. Even taking Great Britain and Ireland together, the loss by emigration per annum has not been very large, as shown by the following table:

### Annual Emigration per 1000 of the Average Population of Great Britain and Ireland.

Even in particular districts where emigration is heavy the loss is made up by births. For instance, in 1891 the emigration from the provinces of West Prussia and Posen was extraordinarily heavy, 10-9 births per 1000 per annum occurring in the province of West Prussia, and 19-6 deaths per 1000 per annum occurring in Posen. If it is assumed that the excess of births over deaths was 19-6 per mille. Emigration may give temporary relief to congested districts, but it is not in itself a remedy for so-called over-population.

It is to be noted that voluntary emigration takes away the cream of the working-classes. It is the man of energy, of some means, of ambition, who takes the chances of success in the new country, leaving the poor, the indolent, the weak and crippled at home. It is maintained that such emigration institutes a process of selection which is unfavourable to the home country.

On the other side, it is said, that those who are doing well at home are not likely to emigrate, because they have least to gain. Modern means of transportation have made the voyage so cheap that almost any one is able to go. It is therefore the restless, the unsuccessful, or at least those not fitted for the strenuous competition of the old world, who lack energy and ambition are most likely to emigrate. Emigration affords a natural outlet for the superfluous labour force of a country. The supply of labour is somewhat reduced, but wages are kept up for those who remain. Those who go find means of bettering their own condition beyond the seas, where there become producers of food and raw material for the home country, and at the same time customers for her manufactured products. Emigration is, therefore, an economic gain, both direct and indirectly.

It is evident from these arguments that the consideration of emigration affords a natural outlet for the superfluous labour force of a country. The supply of labour is somewhat reduced, but wages are kept up for those who remain. Those who go find means of bettering their own condition beyond the seas, where they become producers of food and raw material for the home country, and at the same time customers for her manufactured products. Emigration is, therefore, an economic gain, both direct and indirectly.

### Effects of Immigration.

- **Economic effects:** The economic gain of immigration to many countries is evident. It adds directly to their available labour force, that is, to the number of adults engaged in the work of producing wealth.
- **Political effects:** The political effect of immigration is twofold. On the one hand, it increases the population of the new country; on the other, it has the effect of increasing the number of native whites of foreign parentage.

According to the United States census of 1900, out of 29,072,553 (91%) American-born inhabitants (0-10 years old) of foreign birth, 20-15% were of foreign birth. If we add to these the native whites of foreign parentage (5,300,924) we have 11,152,323 persons of foreign extraction or 39% of the total labour force. The foreign whites alone composed 19% of the total number of persons engaged in agricultural pursuits; 11% of those in professional services; 25-7% in domestic and personal services; 19-2% in trade and transportation; and 35-6% of those engaged in manufacturing and mechanical industries. In addition, 10-8% of those engaged in professional parentage constituted in agriculture, &c., 10-6%; in professional service, 20-6%; in domestic and personal service, 16-4%; in trade and transportation, 25-7% in manufacturing and mechanical, 25-4% of all those engaged in those occupations. The labour force of the United States is thus made up very largely of immigrants and the children of immigrants.

Attempts have sometimes been made to put a money value on the economic gain by immigration. The amount of money brought by immigrants is small. On the whole, the average income of the money sent back by immigrants for the support of families and friends at home or to aid them in following. The value of social and political effects may be calculated. Even if we should take as an example the 1882 results, we find that the money sent back by immigrants for the support of families and friends at home or to aid them in following. The value of social and political effects may be calculated. Even if we should take as an example the 1882 results, we find that the money sent back by immigrants for the support of families and friends at home or to aid them in following. It is a matter of fact that from 1869 to 1870, the average yearly income of the foreign-born was $800 to $1000, so that every adult immigrant may be looked upon as worth that sum to the country. On the other hand, it is said that an adult immigrant represents what it would cost to bring up a child from infancy to manhood. For instance, Engel estimates the cost of raising an immigrant from age 0 to age 60 as $550. Multiplying the number of adult immigrants by any one of these factors, we find that the money sent back by immigrants to support families and friends at home or to aid them in following.

The immigrant is worth what it has cost to bring him up only if he is able to support himself. It is estimated that in the United States the cost of bringing up an orphan ranges from $500 to $1000. A child is a liability instead of a gain. So, too, the immigrant is worth his future net earnings to the community only if there is a demand for his labour.

### Social and Political Effects of Immigration.

The influx of millions of persons of different nationalities, often of a foreign language and generally of lower classes, was to be a danger to the homogeneity of a community. The United States, for instance, had come to be a melting pot, or simply from the desire to get rid of undesirable members of the community. Such efforts fail if the new countries are unwilling to admit these persons. Finally, we have the expulsion of the Jews from Russia as an example of the effort of a community to get rid of an element which has made itself obnoxious to the local sentiment.
MIGRATION

Some law of international comity is violated by the refusal to receive these unfortunate. They shall be taken care of at home. The English policy in 1905 passed the law to prevent the landing of undesirable aliens, and the number refused admission in 1906 was 493. (b) Immigration sometimes increases the competition in the labour market, and thus lowers wages. One case is particularly aggravating, viz. when employers import foreign labourers in order to take the place of their men who are on strike. In 1885 the United States passed what is called the Contract Labor Law, forbidding the landing of any person who is under contract to perform labour in the United States. It is very difficult to discover such cases, but the number rejected is fairly large (see table above).

(c) The immigration of men of alien race who refuse to associate with the natives is said sometimes to be a danger to the country. This at least is the excuse for the entire exclusion of Chinese labourers from the United States since 1882 (provisions made more severe in 1888 and 1892) (see all the article 190118).

Internal Migration.—In modern times there is constant movement of population within national lines, from section to section, and especially from rural districts to the cities. No record is kept of this, and we can trace it only through the census statistics of birthplaces. In the United States it is known that it was in 1890, when more than 21.5 per cent. of the native-born inhabitants were living in a state other than that in which they were born. Still further, it appears that about one-half of the native-born inhabitants had moved out of the country in which they were born. In 1890 there were 1,233,629 natives of the state of New York living in other states. The movement is principally westwards in direction and along parallels of latitude. For instance, New York has made large contributions to the population of Ohio, Michigan, Illinois, Wisconsin, Iowa, and so on. Virginia has contributed largely to the population of West Virginia, Kentucky, Ohio, Indiana, Illinois and Missouri. In Europe there is a similar movement; but it is difficult to make comparisons, because of the differences in the administrative areas. In England it is known that about 16 per cent. of the population were residing in their native county; in Prussia, 60.7 per cent. in the Kreis; in France, 81.7 per cent. in the département; in Austria, 80.2 per cent. in the Bezirk; in Switzerland, 82.1 per cent. in the canton where they were born (Weber, Growth of Cities, p. 249). The most important phase of internal migration is the movement from the rural districts to the cities. The statistical results are shown in the following table extracted from the admirable work of Weber, just quoted:

Percentage of Population living in Towns of 10,000 and over at Three Periods.

Somewhat the same phenomenon is seen in France. According to the census of 1891, not less than 35 out of the 67 departments had lost population, and out of the 32 that had increased, 7 showed a decrease in their rural parts when the large towns were deducted. In Germany the towns of 10,000 and over show a much more rapid increase than the rural districts; and the same fact is generally true of the other countries of Europe. This more rapid increase of population in cities is due not only to immigration from the country. Until the 19th century deaths generally exceeded births in cities, so that if it had not been for constant immigration the cities would not only not have grown, but would have decreased in population. Cities grow more rapidly now than formerly, because the excess of deaths over births has been turned into an excess of births over deaths. Thereby the cities are becoming less dependent upon immigration for increase of population than formerly, but the migration still goes on. The causes of migration from country to city are mainly economic. In early stages of culture men are scattered over the country, or at most gathered together in hamlets and villages. Each of these is self-sufficient, having its own artisans and handicraftsmen, and producing what it needs. With the beginning of exchange commercial centres spring up, situated at navigable streams and especially at points where land and water journeys are broken. With the growth of manufactures, industrial centres spring up where the division of labour can be fully provided for. In modern times two factors have accelerated this process, viz.: (1) the building of railways, which have developed commerce to a very great degree and favoured the large towns at the expense of the small; and (2) the invention of machinery, which has greatly increased the possibility of division of labour and manufactures on a large scale. The handicraftsman has been superseded by machine labour and the village artisan by the factory hand. At the same time improvements in agriculture and the opening up of new countries have enabled the modern community to gain its food and raw material with a less expenditure of labour force, and the surplus agricultural population has gone to the city. The attractive influences upon individuals have been higher wages, greater scope for the ambitious, and the social advantages of city life.

The general laws of internal migration may be summarized (according to Ravenstein) as follows:

1. The great body of migrants proceed only a short distance.
2. The process of absorption goes on as follows: The inhabitants of the country immediately surrounding a town of rapid growth flock into it; the gaps thus left in the rural population are filled up by movements from remote districts, until the attractive force of one of the rapidly-growing cities makes its influence felt, step by step, to the most remote corner of the land. Migrants enumerated in a certain centre of absorption will consequently grow less with the distance, proportionately to the native population which furnishes them.
3. The process of dispersion is the inverse of that of absorption, and exhibits similar features.

Everywhere the city population is increasing faster than the rural. In the United States the rate of increase per decade was as follows:

<table>

MIGRATION

4.33

4. Each main current of migration produces a compensating countercurrent.
5. Migrants proceeding long distances generally go by preference to one of the great cities of commerce or industry.
6. The natives of towns are less migratory than those of the rural parts of the country.
7. Females are more migratory than males.

Authorities.—The statistics of migration are to be found in the annual reports of different countries, especially the statistical tables relating to emigration and immigration published by the British Board of Trade, and the Reports (annual) of the Commissioner-General of Immigration of the United States. For general discussion of migration, Philipps, Auswanderung und Auswanderungspolitik (Leipzig, 1892). An exhaustive bibliography will be found in an article by same author, "Auswanderung," in Handwörterbuch der Staatswissenschaften: R. Mayo-Smith, Emigration and Immigration, with bibliography (New York, 1890). For internal migration see Albert, "Laws of Migration," in Journal of Royal Statistical Society (1885 and 1886). Professor Flinders Petrie, in his Huxley Lecture for 1906 on Migrations (reprinted by the Anthropological Institute), deals with the mutations and movements of races from an anthropological standpoint with profound knowledge and originality. (R. M.-S.; T. A. I.)

Migration, in Zoology. In zoology considerable importance attaches to the problems of migration, by which is meant the wandering of living creatures from one place to another, usually distant, locality in order to breed there; this implies a return, and the double phenomenon is annual. All other changes of the abode are either sporadic, epidemic, or fluctuating within lesser limits. Further, migration should not be confounded with "spreading," which proceeds steadily, and in epicycles, with a totally different result. It need not be emphasized that hard and fast lines between these phenomena do not exist; they are often a question of degree. For instance, when the common toad, which is a strictly terrestrial creature, wanders every spring to a frequently distant pool in order to spawn there, this is a true migration. The same applies, strictly speaking, to those insects which hibernate in the ground, at the root of the tree on which they feed and breed. The grey plover breeds in the arctic circle and winters in equatorial countries. To complicate matters further, it is not necessary that the migration be undertaken periodically, more than once, by the same individual. For instance, the common eel ascends the rivers as an elver in its youth; then after it returns to the sea, there to breed and die, whilst other fishes come and go, year after year. Further, some of the larger birds, for instance swans and cranes, are still immature in their second year, and yet they migrate like their older relations. It seems permissible to use this fact as an indication that the breeding as such is not the prime reason of their wanderings. The fundamental impelling agent must have been the want of food, and what we usually understand by migration cannot suddenly have sprung into existence to its full extent, but is more likely the cumulative effect of the doings of countless generations. The faculty of shifting the abode was of course always there, the necessity of moving further on was also present, and those which went in the wrong direction came to grief, while the others flourished and returned with their progeny. They did not at first cover enormous distances, but just enough to find an unoccupied ground. The annual repetition became an established habit, at last an ineradicable instinct. There can be but little doubt that the prime impulse was want of food. The new growing grass on the prairie or on the veldt attracts every year those creatures which live upon pasture. The inter-tropical belt of the world is so crowded with creatures that there is the keenest competition, whilst in the temperate and cold regions is a long winter quiescence unfit for the support of many creatures, whereas in the summer these same regions are covered with new vegetation, with its concomitant abundance of insects and other invertebrates. The tables are decked again, and these opportunities are not wasted.

The process of migration, in its most striking cases, is now very complicated. Many a bird goes actually to the arctic regions for the shortest of summers, but spends most of the year within the tropics. On the other hand there are many species which do not go so far north, but stop to breed in the intermediate regions. We must not take the extremes when trying to unravel the development of the problem. The periodical migrations of mammals, with their more limited extent and greater leisure, are less perplexing.

It has been argued with some show of reason that the real home of a bird is that country in which it was born, in other words where the species breeds, but this is not in every case a valid conclusion. It applies to most creatures, but it can well bear exceptions if we leave sentiment aside. When it comes to a question of domicile, the ten weeks' sojourn of the swift, Cypselus, in England are more than weighted down by the nine months or more which these birds spend in southern countries, although we do not know whether they are resident there or roam about. The breeding time is the busiest period of a bird's life; then the numbers of each species are suddenly multiplied, and so is the stress of providing food, and the particular food which is best for the young may not be available in every country. The idea that the arctic circle is the original home of the numerous kinds of birds which breed in it, whence they are now periodically driven away by stress, has been coupled with the glacial epoch, that supposed solution of so many difficulties. We have only to assume that the old, permanent home of some of these migrants was in the arctic region, that the progressing glaciation drove them away, of course towards the equator, and that, when times improved again, the birds returned to their old home. This sounds very plausible, but it involves huge assumptions. The birds, not the individuals, but the species, are supposed to have inherited such a loving reminiscence of their old home, that after thousands of years—with most of the small birds meaning as many generations—they returned at the first opportunity. It implies that their long continued sojourn in foreign lands, where—under this assumption—thousands of generations must have been bred and have spent all their lives, was not sufficient to naturalize them, so to speak, in other words to supplant the instinctive love of the primary ancient home. That the last glacial epoch has driven the limit of many kinds of animals and plants farther south is as certain as that many have recovered the lost ground after the reversion of the glaciation, but it must have been a very slow and gradual process of spreading. It may, and probably does, account for the present manner of migrations, as a phenomenon which has been evolved de novo, which would have come to pass even if no birds had existed in pre-glacial times.

How do birds manage to find their way, thousands and thousands of miles across land and water? This question has been entangled as a mystery of mysteries. It has been stated that the old birds show the way to the young, a speculation which does not apply to those many cases in which old and young notoriously travel at different times. It has been assumed that they travel by sight, taking advantage of certain landmarks; another untenable idea, since—experience having to be excluded in a flock of birds which made the journey for the first time—it implies that the young must have inherited the reminiscence of those landmarks! Others have likened the bird to a kind of compass, because in eastern Siberia E. von Middendorff found some migration routes to coincide with the direct line of the magnetic pole. The whole question reduces itself to a sense of direction, a faculty which is possessed by nearly all animals; in some it is present to astonishing extent; but the manifestations of this sense vary only in degree. The cat which escapes out of the bag finds its way back, directly or after many adventures. The bee, after having loaded itself with pollen, returns by the proverbial line to the hive which may be a mile away, but, move the small entrance hole in the meantime an inch to the right or left, and the bee will knock its head against the hive and blunder about; move the hive a few yards and bee after bee returning will be puzzled to find its hive again. They, maybe with the help of landmarks, have accustomed themselves to steer a course. Such instances need not be multiplied. The principle is the same whether
The journey be one of a few yards or of many miles. Given the sense of direction, it is no more difficult to steer a course due north than it is to lay one south-east by east, provided always the impetus to be on the move. There is no mystery, except that we, the most intellectual of mankind, should so well nigh have lost this sense, and even this fact is simply an instance of the loss of a faculty through long-continued disuse.

Birds.—(The following account is to a great extent based upon A. Newton's article "Birds" in Engly. Brit., 9th ed.)

There are many species which arrive in spring, remain to breed, and depart in autumn; others which arrive in autumn, stop for the winter and depart in spring; and others again—and these are strictly the "birds of passage," which pass through the country without staying long in it, and their transient visits take place about spring and autumn. These three apparently different categories of migrants are all acted upon by the same impulse in spring, to pass down to the south, or to the north, or to the south-east of them, and thus perform on a much smaller scale the great migration of other species.

The species which resort to Britain and to other temperate countries in winter are simply those which have their breeding quarters much nearer the poles, and in returning to them on the approach of spring are but doing exactly as do those species which leave their winter abode nearer the equator, come to us with the spring.

The birds of passage proper, like our winter visitants, have their breeding quarters nearer the pole, but like our summer visitants, they seek a shorter equatorial equator and thus perform on a much smaller scale the great migration.

As H. Seebohm puts it (Geograph. Distr. of the family Charadrii, London):

"They all represent birds which breed in the north and winter in the south. Every migratory bird wintering in England goes north to breed, and is therefore a migratory creature, and the colder it goes south to winter, it is a rule without exception in the northern hemisphere that each bird breeds in the extreme north point of its migrations. To make the rule apply to the southern hemisphere, we only need to reverse the direction, and the coldest climate which it visits on its migrations... It is a remarkable fact that whilst there are many birds breeding in the northern hemisphere and wintering in the southern, it is not known that there are any birds breeding in the southern hemisphere and wintering in the northern! This is probably owing to the difference in the distribution of the land, there being no Antarctic breeding grounds.

Birds breeding in the tropics are always resident, except when subjected to local influences, and the climate causes them to descend into the valleys for the winter."

In many countries we find that while there are some species, such as in England the swallow or the fieldfare, of which every individual disappears at one period of the year or another, there are other species, such as the pied wagtail or the woodcock, of which only the majority of individuals vanish—a few being always present—and these species form the so-called "partial migrants." In the Pied Wagtail there is always a constant remittance from some species on the accession numbers from the birds which arrive from the north, though the migration is by no means so well marked as it is on the continent, where the arrival of the strangers sets all the followers at work. In most localities in Britain the newcomers depart after a short sojourn, and X. Bervière has been able to show that some of the bred birds that in some parts of the island it may be safely declared that not a single song-thrush can be found from the end of November to the end of January, while in other examples can always be seen. Much the same may be said of the redstart. Undoubtedly resident as a species, attentive scrutiny will reveal the fact that its numbers are subject to very considerable variation, according to the season of the year. At no time do our redstarts collect in bands, but towards the end of summer they may be seen in the south of England, successively passing onward, the travellers being mostly—if not wholly—young birds of the year; and so the great majority disappear, departing it may be safely presumed for more southern countries. It is the custom of later years, and of birds bred in France and then in Italy, are well supplied with this species. But the migratory influence affects, though in a less degree, many if not most of the redstarts that remain with us. Every bird of this kind can be considered to a greater or less degree migratory in some part or other of its range.

Want of food, and perhaps of the special, proper kind during the breeding season, seems to be the most obvious cause of migration, and is a cause which has been well accounted for by those who have done of removing themselves from a place of scarcity should avail themselves of it, while it is unquestionable that birds possess this faculty in the greatest degree. Even among those species which we commonly regard as migratory by it they can remain on their ground throughout the year. It has long been known that birds-of-prey customarily drive away their offspring from their own haunts so soon as the young are able to shift for themselves. The practice, however, is not limited to the birds-of-prey alone, but is much more universal. We find it to obtain with the red-bread, and if we watch our feathered neighbours closely we shall perceive that most of them indulge in it. The period of expulsion, it is true, in some birds deferred from the end of summer or the autumnal equinox, which has been demonstrated with great effect when indeed from the maturity of the young it must be regarded as much in the light of a voluntary secession on their part as in that of an act of parental compulsion, but the effect is ultimately the same.

The mode in which the want of sustenance produces migration may be best illustrated by confining ourselves to the unquestionably migratory birds of our own northern hemisphere. As food grows scarce towards the end of summer in the most northern limits of the range of a species, the individuals affected thereby seek it elsewhere. Thus doing, they press upon the haunt of other individuals: these in like manner upon that of yet others, and so on, until the migration which began in the far north is communicated to the south. As a result of this gradual progression the species at that season; though, for such an intrusion, these last might be content to stay some time longer in the enjoyment of their existing quarters.

Birds seem satisfied to extend the southward movement of all migrating birds in the northern hemisphere; but when we consider the return movement which takes place some months later, doubt may be entertained whether scarcity of food can be regarded as the sole cause, and thus our edition not to come to any decision on this point. On one side it may be urged that the more equatorial regions which in winter are crowded with emigrants from the north, though well fitted for the resort of so many individuals, are not capable of yielding food for them all; and this computation twice as numerous as the former—unless the numbers of both were diminished by the casualties of travel. But on the other hand we must remember what has above been advanced in regard to the intensity of the emigration in the south, and the reduced breeding-places, and the force of this passionate fondness for the old home cannot but be taken into account, even if we do not allow that in it lies the whole stimulus to undertake the perilous journey.

A. R. Wallace in some remarks on the subject (Nature, x. 459) ingeniously suggests the manner in which the habit of migration has come to be adopted:

"It appears to me probable that here, as in so many other cases, such as those of the fir tree, that we have found to have had a powerful influence. Let us suppose that in any species of migratory bird, breeding as a rule only fairly accomplished in a given area, and further, that during a great part of the year sufficient food cannot be obtained in that area... It will usually that those which do not leave the breeding area at the proper season will suffer, and ultimately become extinct; which will also be the fate of those which do not leave the feeding area at the proper time. Now suppose that a desire (such as the desire of the existing species coincident, but by geological and climatic changes gradually diverged from each other, we can easily understand how the habit of incipient and partial migration at the proper season was to be gradually developed, until it came to be regarded as an instinct in all species. It will probably be found that every gradation still exists in various parts of the world, from a complete coincidence to a complete separation of the breeding and the subsistence areas, and from the natural history of a sufficient number of species thoroughly worked out we may find every link between species which never leave a restricted area in which they breed and live the whole year round, to those other cases in which the two areas are absolutely separated."
should outstrip the weaker by a very perceptible distance, and it can hardly be doubted that in most species the males are stronger, as they are bigger than the females. Some observers assert that the same thing takes place in the return journey in autumn—Seebohm (ibid., p. 276) states that the males of the shoveller have been seen to arrive in the southern parts of their range before the females. Thus, after the females, having finished their molt of autumn, and lasting the females—but on this point others are not so sure, which is not surprising when we consider that the majority of observations have been made by ornithologists, whereas it is the work of Fratercula Passeres, to which the remark is especially applicable—in the British islands, France, North Germany and the Russian empire, it is flat that at the beginning of the journey any inequality in the sexes is not to be observed, but the males have the same so very innate characteristic. It is also another matter to be noticed. It has been suspected that there is no difference in the size of birds of the same species, particularly in the dimensions of their wings, the individuals that have been observed show no particularly marked feature, the longest and broadest remnants, and in support of this view it certainly appears that in some of the smaller migrants—such as the wheatear (Saxicola oenanthe) and willow-wren (Phylloscopus trochilus)—the examples which reach the south possess greater mechanical powers of flight than those of the same species which stop short on the shores of the Mediterranean. It may perhaps be also inferred, though precise evidence is wanting, that these individuals push further to the southward in winter than do those which are less favoured in this respect. It is pretty nearly certain that such is the case with some species, and it may well be so with individuals. H. B. Tristram and E. von Middendorff have made observations in the north of Spain, and it would be difficult to deny that the winter flights of these species show a more southerly extension than they have made about the weather in the places whence the travellers are supposed to have come. As a rule it would seem as though birds were not dependent on the weather to any great degree. Occasional achievements of the kind are known, but it is somewhat delayed, but most sea-fowls may be trusted, is said, as the almanac itself. Foul weather or fair, heat or cold, the puffins (Fratercula arctica) repair to some of their stations punctually on a given day as if their movements were regulated by some clock. Whether they have come from far or from near we know not, but other birds certainly come from a great distance, and yet make their appearance with scarcely less exactness. Nor is the regularity of their autumnal departure connected with this, for every observer knows how abundant the swift (Cypselus aequalis) is up to the time of its leaving its summer-home—in most parts of England, the first day of August—and how rarely it is seen after this day.

It must be allowed, however, that, with few exceptions, the mass of statistics above spoken of has never been worked up and digested so as to allow proper inferences to be made from it, and therefore it is premature to say that little would come of it, but the result of those exceptions is not very encouraging. E. von Middendorff carefully collated the records of the arrival of migratory birds throughout the Russian Empire, but the insight into the question afforded by his published labours is not very complete. Chiefly has been to trace what he has termed the iseppeises (los = aequalis, et = reddat = adovolus) or the lines of simultaneous arrival, and in the case of seven species these are laid down accurately. These was found by taking the average date of arrival of species of each place in the Russian dominions where observations have been regularly made, and connecting those places where the dates are the same. The lines which emerge on these maps indicate the inequality of progress made by the species in different longitudes, and assuming that the advance is directly across the iseppeises lines, or rather the belts defined by each pair of them, the result is said to be very satisfactory. E. von Middendorff says, "The chief fact is that, by the method of the iseppeises, I have been able to trace boundary lines for the distribution of the species, so that the knowledge of landmarks, is utterly insufficient to account for the success that attends birds which travel by night, or in a single flight span oceans or continents. Yet without it the idea of 'experience' cannot be substantiated. We may admit that instinct but unconscious experience, which is really all that can be meant by instinct, is a factor in the whole matter—certainly, as Wallace seems to have proved, in originating the migratory impulse, but yet it is not the direct aspect of the question.

Less than nothing is known about the speed at which birds fly during their long stretches of migration. Gaetke, in his otherwise very interesting book, has started ornithologists by various statements and inferences. He attempted to calculate the rates of migration from the known miles and distances, and from the assumption that the results are ridiculous. For instance, he proved to his satisfaction that the grey or hooded crow, Corvus cornix, which notoriously is not a fast bird, flies from Heligoland to the coast of Labrador in three and a half days in an average wind of ten miles an hour. To the little blue-bunting he assigned a velocity of two hundred and forty miles an hour, a statement as silly as that of the "Turtle-doves leaves Kent or Surrey at dawn might easily be the very birds that a few hours later were skimming over the Portuguese pine forests on their way to Central Africa." Fifty or one hundred miles an hour with the aid of the thermals, and there are no reliable data to tell how long such birds can continue their flight without interruption. All we seem to know is that not a few kinds manage, in various parts of the world, to cross the open sea without the assistance of a boat, and that what Gaetke's notion that migration was for the most part carried on at such a height in the air as to be beyond our ken, and that what
comes to our perception consists chiefly of the abortive or unsuccessful
attempts, when birds are checked in their course, and being unable to proceed present themselves to our sight and hearing.

Now for obvious reasons birds could not well fly at very great height, since the particles of air, as experiments with balloons have shown, and the conducer soaring far above the tops of the Andes is a myth. The few trustworthy instances in which birds have been observed through a telescope passing across the face of the sun are of such natural and indirect origin, as to distance and height. W. E. D. Scott (Bull. Nuttal Orn. Club, vi. 97–100), computed heights varying from 1 to 2 m.

F. M. Chapman’s observations (Auk, 1888, pp. 37–39) resulted in a height of from 15 to 16 ft.; average, say, 1 m. If the bird was observed to be really aloft in the sun, it probably proceeds beyond our ken, and if for some reason or other they are below the clouds the phenomenon becomes to us very noticeable.

It is well known that clear and bright nights birds are rarer, and that their flight is with difficulties seen. We observe that an overhead misty and dark, especially if slight rain be falling, flocks may often be heard almost continuously. It is in such weather, continues Newton, that birds while migrating are most vociferous, doubtless with the result that thereby the company of fellow-travellers is kept together.

There yet remain a few words to be said on what may be termed Exceptional Migration, that is when from some cause or other the bird seeks a more or less abnormal direction. Several, the various species of crossbill (Loxia) and some allied forms afford perhaps the best-known examples. In England no one can say in what part of the country or at what season of the year he may not fall in with groups or flocks of these birds, which they do for no apparent reason and the like may be said of many other lands. The food of these birds consists mainly of the seeds of conifers, and as its supply in any one locality is intermittent or precarious, we may not unreasonably observe their migrations when they are driven from their native herbage. We may thus find an easy way of accounting for their uncertain appearance.

The great band of nutcrackers (Nucifraga caryocatactes) which in the autumn of 1844 pervaded western and eastern Europe (Bull. Acad. Bruxelles, xi. 298), may also have been actuated by the same cause, but we can hardly explain the roaming of omissions of birds so plausibly. The inroads of the waxwing (Ampelis garrulus) have been the subject of interest for more than 300 years, and by persons prone to superstitions auguries, and others as fore-runners of the harvest. So comical an occurrence, where the bird being seen in central, western or southern Europe, and then perhaps for two or three seasons in succession vast flocks have suddenly appeared. Later observation has shown that this species is not uncommon in Europe in winter, and the occurrence of one or a dozen at the most may be considered as natural. The bird has been described as having a soft voice, and the call by the name of ‘mew’.

One of the most extraordinary events known to ornithologists is the irruption into Europe in 1863 of Pallas’s sand-grouse (Syrrhaptes paradoxus). Of this bird, hitherto known only as an inhabitant of the remote steppes of southern Siberia, we hear in the years 1860 to 1865 of flocks from the west, and in the south extending to Sicily and almost to the frontiers of Spain. On the sandhills of Jutland and Holland some of these birds bred, but they were all killed off. A much greater visitation took place in the year 1870, when the number of birds was quite incalculable, the wave extending from Norway to southern Spain.

In comparison with the periodic annual migrations of so many birds, those of other creatures are scarce and insignificant, except in certain cases.

Mammals.—Few trustworthy observations have been recorded. The most regular and least limited migrations seem to be those of the eared seals. The walrus also goes each year to the north in the spring and returns in the autumn to the breeding-grounds. One of the Cetacea, ascends the Amur regularly on the breaking of the ice, a distance of 400 m. upper stream. Some bats are supposed to migrate. The American bison used to roam north and south in vast numbers, and similar periodic wanderings have often been recorded of various kinds of game on the South African veld. They are all obviously a more matter of commissariat and have little to do with the breeding of species.

In one way the lemming’s “migrations” are instructive. They are quite sporadic. When, owing to combination of some favourable circumstances they suddenly increase, enormous numbers forsake their homes, and in doing so behave in a methodical way, but quite lawlessly; that means to say they radiate from their centres of dispersal. At any given spot, however, they seem to keep to the same direction, and no obstacles seem to divert their course. Those which arrive at the most inundated are known even to rush into the sea, where of course they get drowned. There is no sense in this. The overcrowded condition of their home impels them to leave, and this impulse continues blindly. They do not attempt to settle anywhere between their home and the sea. A year or two after the irruption not a lemming is there to be found, and where during their stampede they come across hills, rivers, lakes, and even in villages and farms, they suffer, especially when such a country possesses already kindred fauna of its own.

Fish.—Many fishes make periodic migrations for breeding purposes, which, by their numbers and the distances travelled, are remarkable. The salmon of the Columbia river begins running in the spring freshets in March and April. It spends the whole summer, without feeding, in the ascent of the river. By autumn the individuals are observed to have reached the mountain streams of Idaho, greatly increasing in numbers. Soon they are observed in the mouths of the larger rivers, and are observed to arrive in the spawning-grounds, which may be 1000 m. from the sea in the Columbia, over 2000 m. in the Yukon, the female deposits her eggs in the gravel of some shallow brook. The male covers them up and the gravel over them. Then both male and female drift, tail foremost, helplessly down the stream; none, so far as certainly is known, ever survive the reproduction act. The same habits are found in the five other species of salmon in America. The eel (Anguilla anguilla) has the particular character of being in England anadromous, i.e. their usual habitat is in rivers and lakes, but they descend into the sea for breeding purposes.

The common eel is the classical example.

Insects.—D. Sharp makes the following remarks (Cambridge Nat. Hist. of Entomology, 1882–1891): "A few of the insects known to form swarms and migrate. Swarms of this kind have been frequently observed in Europe and in North America; they usually consist of a species of the genus Libellula, but species of various genera of Orthoptera, and sometimes a swarm may consist of more than one species."

Locusts do not visit the districts that are subject to their invasions every year, but as a rule only after intervals of a considerable number of years. The irregularity seems to depend on the occurrence of specific conditions, which may be kept in check by parasitic insects; that the eggs may remain more than one year in the ground and yet hatch out when a favourable season occurs, and that the migratory instinct is only effective when great numbers of locusts are present, is well established. The swarm is a matter of scientific interest, and is one of the points which have been most studied. When migration of locusts does occur it is attended by remarkable manifestations of instinct. Although several generations may elapse without a migration, it is believed that the locusts when they do so in the direction taken by predecessors. They are said to take trial flights to ascertain the direction of a favourable wind. The resulting discovery that the most obscure point is their disappearance from a spot they have invaded. A swarm will alight on a locality, deposit there a number of eggs, and then move on. But after a lapse of a season or two there will be a recrudescence of the swarm, when in one or other of the cases they again migrate after growth to the land of their ancestors. It has been ascertained by the United States Entomological Commission that such return swarms do occur."

J. H. Palmer, Polia, Vogelquartett (Leipzig, 1874). The common names in German: Der Vogelquartett (Leipzig 1896). In this and the work of von Middendorf, already

MIJUEL, MARIA EVARIST (1802–1866), usually known as Dom Miguel, whose name is chiefly associated with his pretensions to the throne of Portugal, was the third son of King John VI. of Portugal, and of Carlota Joaquina, one of the Spanish Bourbons; he was born at Lisbon on the 26th of October 1802. In 1827 he accompanied his parents in their flight to Brazil, where he grew up an uneducated and fanatical debaucher; in 1831, on his return to Europe, it is said that he had not yet learned to read. In 1822 his father swore fidelity to the new Portuguese constitution which had been proclaimed in his absence; and this led Carlota Joaquina, who was an absolutist of the extreme Bourbon type, and hated her husband, to seek his dethronement in favour of Miguel her favourite son. The insurrections which ensued (see PORTUGAL) resulted in his imprisonment and the exile of Miguel (1824), who spent a short time in Brazil and afterwards lived in Vienna, where he came under the teaching of Metternich. On the sudden death of John VI. in May 1826, Pedro of Brazil, his eldest son, renounced the crown in favour of his daughter Maria da Gloria, on the understanding that she should become the wife of Miguel. The last named accordingly swore allegiance to Pedro, to Maria, and to the constitution which Pedro had introduced, and on this footing Miguel, returning to Portugal in July 1827, took the throne on the 1st of February 1828, and, regardless of his promises, dissolved the new Cortes in March; having called together the old Cortes, with the support of the reactionary party of which his mother was the ruling spirit, he himself proclaimed sole legitimate king of Portugal in July. His private life was characterized by the wildest excesses, and he used his power to oppose all forms of liberalism. The public opinion of Europe became more and more actively hostile to his reign, and after the occupation of Oporto by Dom Pedro in 1832, the destruction of Miguel's fleet by Captain (afterwards Sir Charles) Napier off Cape St Vincent in 1833, and the victory of Saldanha at Santarem in 1834, Queen Christina of Spain recognized the legitimate sovereignty of Maria, and in this was followed by France and England. Dom Miguel capitulated at Evora on the 27th of May 1834, renouncing all pretensions to the Portuguese throne. He lived for some time at Rome, where he enjoyed papal recognition, but afterwards retired to Bronnbach, in Baden, where he died on the 14th of November 1866.

MIHRAB, a term in the Mahomedan architecture given to the niche in the wall of a mosque indicating the direction of Mecca, towards which the Moslems turn when praying.

MIKADO (Japanese for "exalted gate"), the poetical title associated by foreign countries with the sovereign of Japan; the Japanese title, corresponding to "emperor," is tenno, the term kotei being used of his function in relation to external affairs. By the constitution of 1889, the emperor of Japan transferred a large part of his former powers as absolute monarch to the representatives of the people, but as head of the empire he appoints the ministers, declares war, makes peace and concludes treaties, acting generally as a constitutional sovereign but with all the personal authority attaching to his august position. The history of the mikados goes back to very early times, but from 1600 to 1868 the real power was in the hands of the shoguns, who nevertheless were in ceremonial theory always successively invested with their authority by the mikado. The revolution of 1867 restored the real power into the mikado's hands. (See JAPAN: History; and MIYOSHI—HITO.)

MIKIRS, a hill tribe of India, occupying two or three detached tracts in Nowgong and Sibsagar districts of Eastern Bengal and Assam, known as the Mikir hills. In 1901 their total number was returned as 87,036. Mikir is the name given to them by the Assamese; they call themselves Arleeng, which means "man" in general. They have long settled down to agriculture, and are distinguished from the tribes around them by the absence of savagery. Their language, which has been studied by missionaries, seems to connect them with the Kuki-Chin stock on the Burmese frontier.

MIKLOSICH, FRANZ VON (1815–1891). Austrian philologist, was born at Lutterberg, Styria, on the 29th of November 1815. He graduated at the university at Graz as a doctor of philosophy, and was for a time professor of philosophy there. In 1838 he went to Vienna, where he took the degree of doctor of law. He devoted himself, however, to the study of Slavonic languages, abandoned the law, and obtained a post in the imperial library, where he remained from 1844 to 1862. In the former year he published a noteworthy review of Bopp's Comparative Grammar, and this began a long series of works of immense erudition which completely revolutionized the study of Slavonic languages. In 1849 Miklosich was appointed to the newly created chair of Slavonic philology at the university of Vienna, and he occupied it until 1886. He became a member of the Academy of Vienna, which appointed him secretary of its historical and philosophical section, a member of the council of public instruction and of the upper house, and correspondent of the French Academy of Inscription. His numerous writings deal not only with the Slav languages, but with Rumanian, Albanian, Greek, and the language of the gypsies. Miklosich died on the 7th of March 1891.

MILOTAN (Ital. Milano, Ger. Mailand, anc. Mediolanum, g.), a city of Lombardy, Italy, capital of the province of Milan, 93 m. by rail E.-N.E. of Turin. Pop. (1881), 312,839; (1906), 560,613. It is the seat of an archbishop, the headquarters of the II. army corps, the chief financial centre of Italy and the wealthiest manufacturing and commercial town in the country. It stands on the little river Olona, near the middle of the Lombard plain, 400 ft. above sea-level.

The plain around Milan is extremely fertile, owing at once to the richness of the alluvial soil deposited by the Po, Ticino, Olona and Adda, and to the excellent system of irrigation. Seen from the top of the cathedral, the plain presents the appearance of a vast garden divided into square plots by rows of mulberry or poplar trees. To the east this plain stretches in an unbroken level, as far as the eye can follow it, towards Venice and the Adriatic; on the southern side the line of the Apennines from Bologna to Genoa closes the view; to the west rise the Maritime, Cottian and Graian Alps, with Monte Viso as their central point; while northward are the Pennine, Helvetic and Rhaetian Alps, of which Monte Rosa, the Saasgat and Monte Leone are the most conspicuous features. In the plain itself lie many small villages; and here and there rise the ruins of ancient villages, on or near the hill-top, buildings like the Certosa of Pavia makes a white point upon the greenery. The climate is changeable and trying; in summer it is intensely hot, in winter very cold. Snow is often seen, and the thermometer is frequently below freezing-point.

In shape Milan is a fairly regular polygon, and its focus is the splendid Piazza del Duomo, from which a number of broad modern streets radiate in all directions. These streets are connected by an inner circle of boulevards, constructed just outside the canal, which marks the site of the town moat. The
The arches of Porta Nuova are almost the last trace of the inner circuit, constructed after the destruction of the city by Frederick Barbarossa, to which also belonged the Porta del Pabbi, demolished in 1900. Curious reliefs from the Porta Romana are to be seen in the museum. Within this circle the majority of the structures are narrow and crooked, while those between it and the bastions, though broader on the whole, have but little regularity.

An outer circle of boulevards, planted with trees and commanding the view of the suburbs, lies just beyond the present walls of the city, erected by the Spaniards in the 16th century; the entire length of these boulevards is traversed by an electric tramway 7 m. long.

Occupying one end of the Piazza del Duomo is the famous cathedral. It is built of brick casced in marble from the quarries which Gian Galeazzo Visconti gave in perpetuity to the cathedral chapter. It was begun in 1386. The name of the original architect is unknown, but it is certain that many German masters were called to Milan to assist the Italian builders. It was then the largest church in existence, and now, after St. Peter's at Rome and the cathedral of Seville, the Duomo of Milan is the largest church in Europe; it covers an area of 14,000 sq. yds., and can contain 12,000 people. The interior is 486 ft. long; the nave is 157 ft. high, and the distance from the pavement to the top of the tower is 356 ft. The style is Gothic, very elaborately decorated, but it shows many peculiarities, for the work was continued through several centuries and after many designs by many masters, notably by Amadeo, who carried out the octagonal cupola (the pinnacle of which dates from 1774), and by Tibaldi, who laid down the pavement and designed a baroque façade. This last feature was begun after Tibaldi's design in 1615, but was not finished till 1685, when Napoleon caused the work to be resumed. With its Renaissance windows and portals this façade, though good in itself, was utterly out of keeping with the general style of the church, and in 1900 the removal of the inharmonious features was begun, to be replaced in a style strictly in accordance with the Gothic style of the rest of the building from the designs of Giuseppe Mengoni. In shape the church is cruciform, with double aisles to the nave and aisles to the transepts. The nave is supported by fifty-two pillars with canopied niches for statues instead of capitals; the great windows of the choir, reputed to be the largest in the world, are filled with stained glass of 1444. To the right of the entrance is the tomb of Archbishop Heribert, the champion of Milanese liberty, while beside him rests Archbishop Otto Visconti, the founder of that family as a reigning house. The large bronze candelabrum in the left transept is said to be 13th century work. In a crypt under the choir lies the body of the cardinal saint Carlo Borromeo, who consecrated the cathedral in 1577. It is contained in a rock-crystal shrine, encased in silver, and is vested in full pontifical robes blazing with jewels. The roof of the cathedral is built of blocks of marble, and the various levels are reached by staircases carried up the buttresses; it is ornamented with a profusion of turrets, pinnacles and statues, of which last there are said to be no fewer than 4440, of very various styles and periods. In front of the cathedral is a colossal bronze equestrian statue of Victor Emmanuel II.

There are two noteworthy palaces in the Piazza del Duomo. The first is the Palazzo Reale dating from 1772, but occupying the site of the earliest mansion of the Visconit and the Sforza; its great hall is a handsome chamber with a gallery supported by caryatids. Built into the palace is the ancient church of San Gottardo, a Romanesque building which was built by Azzo Visconti in 1328-1339, and was the scene of the murder of Giovanni Maria Visconti in 1412. Its campanile is a beautiful example of early Lombard terra-cotta work. The second palace is that of the archbishops, the fine façade of which is the work of Fabio Magnone. It has an older north colonnade, by some attributed to Bramante, but, like many other buildings, without sufficient evidence, and a fine court with double colonnades by Tibaldi, to whom the back façade is due. The Palazzo della Ragione, erected in the Piazza del Mercanti, just west of the Piazza del Duomo, the central point of the medieval city, 1223-1258 by the podestà, Oldrado da Tresenna, whose equestrian monument in high relief adorns it, still exists in fine preservation. It is a brick edifice with a portico on the ground floor and a large hall on the upper. Close by to the south is the beautiful Loggia degli Osii, erected in 1316, with two loggie or open porticoes, one above the other, in black and white marble.

Among the most interesting buildings in Milan is the ancient church of S. Ambrogio. Here St. Ambrose baptized St. Augustine; here he closed the doors against the emperor Theodosius after his soldiers had tried to take possession of it. Here St. Ambrose is buried by the Visconti, and here the Visconti желез themselves to be crowned with the iron crown of Lombardy, and the pillar at which they took their coronation oaths is preserved under the lime-trees in the plaza. The earliest church was built on the site of a temple of Bacchus (it is said), but as it stands it is a Romanesque basilica of the 12th century, recently well restored (like many other churches in Milan), with a brick exterior, like so many churches of Milan and Lombardy, curious galleries on the façade. It is perhaps the most perfect preserved structure of all.

The wooden door belongs to the original 11th century church; it has carvings with scenes from the life of David. In a great silver reliquary (modern) in the crypt lie the bones of St. Ambrose, also of St. Augustine, who was consecrated in this church. The original structure was much altered. The oldest part of the church, the transept and the nave, dates from the 8th century, and the 11th century, but, after a fire, the church was reconstructed in the 12th century. The original church was again burnt down in 1671, and reconstructed again in 1753, and a great part of it had to be reconstructed, including the dome (1574-1591). The chapel of S. Agnello, possibly a part of the original structure, contains mosaics of the 5th or 6th century. In plan the church is an octagon, supported at the corners by four square towers in brickwork, which belong to the original structure. The interior with its two orders is a very fine one, and its influence on Renaissance architecture has been considerable. The church is one of the largest Gothic churches in Milan, with some Romanesque survivals, dates, as it stands, with its campanile, from the end of the 13th century, and has a modern façade in the old style. It has some interesting mosaics, and some notable sculpture of the period (Pietro Portinari), with a good dome and a beautiful frieze of angels, built by Michelozzo in 1456-1458, and continuing the splendid sculptured tomb (a marble sarcophagus with reliefs, supported by statues) of Peter Mocetto (died 1441), Duke of Pisa (1399); the walls of the chapel are decorated with important frescoes by Vincenzo Foppa of Brescia. S. Simpliciano, too, though originally Romanesque, is now in the main Gothic, and has been much altered. S. Vincenzo in Prato (833), now restored to its basilican form, with nave and two aisles divided by columns and apses, and with flat, tall arching on the exterior, which is in brickwork; S. Satiro, founded in 879, which also restored to its original form, with its interesting vestry door is particularly interesting; it is the only church in Milan, that is, a brick building in the plan of a Latin cross, with nave and two aisles with round pillars, with a lofted domed tower, in the so-called Romanesque Transition style, having comparatively slender round pillars and wide vaulting, while the exterior is still quite Romanesque. It was founded in 1135 by St. Bernard and consecrated in 1221. It is interesting as the model for the plan of many other churches in Lombardy, e.g. S. Maria del Carmine and S. Agnello, a large church of the same type, with a fine campanile and two towers.
S. Francesco in Pavia. S. Marco, modernized inside, still retains a beautiful façade of 1254 and a tower—in brick as elsewhere—and contains another tomb by Baldassio. S. Maria Incoronata is unique as a double Gothic church, in the horizontal sense (1451—1489). This last contains several tombs and is a monument to the Gothic style.

Of the secular buildings of the beginning of the 15th century, the most notable is the Palazzo Borromeo, which still preserves its Gothic courtyard. It has a good collection of Lombard pictures. At the present day, the Palazzo Borromeo is the seat of the Academia delle Arti del Disegno, founded in 1766. The Palazzo del Senato, Naviglio, and other princely residences are worth a visit, as are the churches of Santa Maria delle Grazie, built by the Dominicans about 1460, to which the Gothic façade and nave belong. The choir, crossing, and beautiful sixteen-sided dome, with the elegant external decorations in terra-cotta and marble, are by Bramante (c. 1492). Adjoining the church is the convent, long used as barracks. Leading from the fine cloisters, also of Bramante, is the former refectory, on the walls of which Leonardo da Vinci painted his “Last Supper,” a work which is unfortunately in a bad state of preservation.

Farther along the Corso, but nearer the Piazza del Duomo, is San Maurizio, the interior of which is covered by exceedingly effective frescoes by Luini and his contemporaries. The interior was erected by Giovanni Dolcebuono, a pupil of Bramante, to whom is also due S. Maria presso S. Celso (the interior and the baroque façade are by Alessi). Thence the Via Boito leads to the Piazza della Rosa, in which is situated the renowned Biblioteca Ambrosiana, erected in 1603—1609 by Fabio Manzonio, to whom the Palazzo del Senato is also due, rich in MSS. In the same building there is also a picture gallery, in which is Raphael’s cartoon for his fresco in the School of Athens in the Vatican. Situated just within the navigli is the galeria delle statue, containing the famous statue of San Nazaro, which contains Bernardino Laini’s (fl. 1546) masterpiece, the “Martyrdom of St Catherine (“), the Ospedale Maggiore. This institution, which can accommodate 2400 patients, was founded in the 13th century by the Medici, and is one of the finest examples of hospital buildings in Italy. The main building (nine and a half) is surrounded by fine arcades of the 17th century by Ricchini. The entire edifice is covered externally with terra-cotta, and its façade, designed by the Florentine Antonio Averulino (Filarete) and begun in 1457, is superior to any other of the kind in Milan.

The city is rich in works of art, for Milan, with the introduction of the early Renaissance style by Filarete and Michelozzo after 1450, became the home of a Lombard school of sculpture, among the chief masters of which may be mentioned Giovanni Amadeo, or Omodeo,1 of Pavia (1447—1532), Cristoforo Solari, and, the last of them, Agostino Busti, known as Bambaia (c. 1480—1548), whose work may be seen in the cathedrals of Como and Milan and in the Certosa of Pavia. Subsequently, towards the close of the 15th century, the refined court of Lodovico Sforza attracted such celebrated men as Bramante, the architect, Gaufino Franchino, the founder of one of the earliest musical academies, and Leonardo da Vinci, from whose school came Luini, Boltraffio, Gaudenzio Ferrari, Marco d’Oggiono, &c. Later, Pellegrino Tibaldi and Galeazzo Alessi of Genoa (the former a man of very wide activity) were the chief architects, and Leonardo da Vinci the greatest of them all. In the 16th century times Beccaria (1573—1704) was a jurist, Monti (1754—1828) as a poet and Manzon (1785—1875) as a novelist, have won for the Milanese a high reputation.

The picture gallery of the Brera, one of the finest in Italy, occupies an imposing palace with a good courtyard by Ricchini. It was built as a Jesuit college in 1651, but since 1776 has been the seat of the Accademia di Belle Arti, and contains besides the picture gallery a collection numbering about 60,000, and an excellent observatory founded in 1766. The Brera Gallery, the nucleus of which was formed in 1806, possesses Raphael’s famous “Sposalizio,” and many pictures and sculpture by Leonardo da Vinci, Andrea del Sarto, Parmigianino, Paris Bordone, Gentile Bellini, Cima da Conegliano, Bonifazio, Moroni and Carpaccio. Additions are continually made to it.

The Castel Sforzesco, or Castle of Milan, stands in the Parco Nuovo, established by the counts of Visconti. The castle was erected by Galeazzo II Visconti (1335—1378) and demolished in 1474 by the populace after the death of Filippo Maria Visconti. After suffering many vicissitudes and being partially destroyed more than once, it was restored—including especially the splendid entrance pavilion—by Antonio Averulino (Filarete, 1457—1483), destroyed by a powder explosion in 1521—in the 15th-century style

in 1893 sqq., and it is now a most imposing pile. Some of the fine windows with their terra-cotta decorations are preserved. The archaeological museum is housed here on the ground floor; besides Roman and pre-Roman objects it contains fragments of the 9th century church of Sta Maria delle Grazie, the bas-relief of the monument of Bernabò Visconti formerly in the church of San Giovanni in Conca; the tomb of Regina della Scala, the wife of Bernabò; the funeral monument of the Rusa family; the great triumphal arch with the palace of Pigello Visconti between, seats the Brera Museum, the oldest museum in Milan, a work of Michelozzo; a series of Renaissance sculptures, including works by Amadeo Mantegazza, Agostino Busti (surnamed Bambia), including fragments of the tomb of Gianst de' Poli; the works in plastic art of the Veronese, the Lanini’s “Last Supper.”

The finest of the modern thoroughfares of Milan is the Via Dante, constructed in 1888; it runs from the Piazza de’ Mercanti to the spacious Foro Bonaparte, and thence to the Parco Nuvo, the great public garden in which stands the Castello Sforzesco. This park was once a national drilling ground, which was taken over by the municipality with a view to erecting upon it a new residential quarter, rendered necessary by the phenomenal growth of the city during the last twenty-five years of the 19th century. This design was happily abandoned, and around the Parco Nuvo has grown up a new quarter of wide streets, spacious gardens and private villas.

To the north of the castle is the Arena, a kind of circus erected by Napoleon in 1805; while facing the castle on the opposite side of the park is the Arco della Pace, begun by Napoleon in 1807. The Arco della Pace is crowned with the statue of Vittorio Emanuele, the first king of Italy, set up in 1887. The two arcos were connected by an underground motor railway, which is no longer in existence. Beyond the Arco della Pace lies the Certosa, the most interesting of the monastic establishments of Milan, and the chief monastery of theCertosa (1254—1314). The Certosa was founded by the Viscontis, and has a fine church, the church of St John, in which are contained the tombs of several members of the family. The Certosa is now a museum, and contains a large collection of painting, sculpture, and manuscript illuminated books.

The Piazza della Scala is also a place of interest, for it is the site of the Palazzo Reale, the residence of the king of Italy, and contains the famous Teatro della Scala, which is the most important opera house in Europe. The building was begun in 1778 on the site of a church founded by Beatrice della Scala, wife of Bernabò Visconti. The Teatro della Scala is the most important opera house in Europe, and contains a fine collection of pictures, including works by Raphael, Leonardo da Vinci, and others. The building was erected by Giuseppe Mengoni in 1778, and is now the seat of the Royal Opera, which is one of the most famous in the world. The Teatro della Scala is also the site of the important televisio, which is used for the transmission of television programmes to the whole of Italy.

The Palazzo Reale is a fine building, and contains a large collection of pictures, including works by Raphael, Leonardo da Vinci, and others. The building was erected by Giuseppe Mengoni in 1778, and is now the seat of the Royal Opera, which is one of the most famous in the world. The Palazzo Reale is also the site of the important televisio, which is used for the transmission of television programmes to the whole of Italy.

by Lord Rowton in 1894. Sport and sports are provided by a number of clubs, notably the Touring Club Italiano, founded in 1897.

The modern industrial development of Milan, with its suburbs and neighboring towns, such as Monza, Gallarate, Saronno, Busto Arsizio and Legnano, has been noteworthy. Machine-making on a large scale is carried on by firms both large and small, and the construction of locomotives, railway trucks and carriages, steam-boilers and motors, turbines, pumps, metal bridges and roofs. Minor industries are represented by workshops for the production of surgical, musical and geodetic instruments; of telephones and telegraph accessories; dynamos, sewing-machines, bicycles and automobiles. There is also a large carriage industry. In textile industries silk holds the first place. The amount of silk handled and produced in an average year is greater than the entire cotton trade. Spinning and twisting are as highly developed as the weaving industry. Milan is also the centre of the Italian cotton industry. Cotton-weaving, dyeing and printing are extensively carried on. Lithography, typography and zincotype are carried on extensively in Milan, and the city has one of the most important theatrical centres. House industry is still widely diffused in Milan itself, especially as regards working in gold, silver, vulcanite, bronze and leather. The motive power for much of the house industry is supplied by electric turbines and electric motors, which are furnished by hydraulic works at Paderno, 24 m. from Milan; the horse-power is continually being increased owing to new needs. Gas is also much used. Milan is also the centre of the export trade in ready-made clothing, such as ready-made garments, shirts, etc.

The municipal schools of Milan are as well organized as any in Italy, and the exhibition in connexion with them at the great international exhibition of 1906 was of interest. There were, in 1907, 761,900 children of school age, of whom 47,600 were in public schools. Among the holiday classes there were 16,724 older pupils; 2,109,920 free rates and 215,135 paid rates were distributed to 16,526 pupils, and douches were supplied. Pizzoli's Tavolo Psacopco for examining the eyes of children was of great interest. The most notable feature of the exhibition of 1906 held in Milan was of considerable importance, all the leading states of the world taking part in it. The retrospective exhibition of means of transport was interesting in view of the recent opening of the Simplon tunnel, the occasion of the exhibition. Among the most noteworthy exhibits were those of machinery, of automobiles and bicycles, of agriculture, of transports by sea, of modern art and architecture, of Italian home industries, of Milanese wines, which all, the countries exhibiting had their own separate pavilions.

Until 1898 the octroi circle did not extend beyond the walls; but in that year it was found necessary, owing to the growth of the city, to extend the octroi circle, comprising the quarters of Corpo di Santi (a name also applied to the extramural portions of Cremona and Pavia), with their large industrial population. Since that time municipal finance has been in a prosperous condition.

The water supply, from wells some 150 ft. deep in the sub-soil, is fairly good; one of the towers of the Castello Sforzesco is used as a distributing centre, while the sewerage system consists of 48 m. of sewers on the single channel principle, with collectors discharging into the main sewer of the territory of the town.

In 1860 a large cemetery, the Cimitero Monumentale, was opened, but found to be insufficient, it is reserved for important monuments, that of Musocco, 3 m. from the city, being used for general purposes.

History.—(For earlier history see Mediolanum.)—After the establishment of the Lombard capital at Pavia in 569 Milan remained the centre of Italian opposition to the foreign conquerors. The Lombards were Arians, and the archbishops of Milan from the days of Ambrose had been always orthodox. Though the state of the Lombards was weakened by their adherence to Arianism, the Lombards gained for them great weight among the people, who felt that their archbishop was a power around whom they might gather for the defence of their liberty and religion. All the innate hatred of the foreigner went to strengthen the hands of the archbishops, who slowly acquired, in addition to their spiritual authority, powers military, executive and judicial. These powers they came to administer through their delegates, called visitors. When the Lombard kingdom fell before the Franks under Charles in 774, the archbishops of Milan were still further strengthened by the close alliance between Charles and the Church, which gave a sort of confirmation to their temporal authority, and also by Charles's policy of breaking up the great Lombard fiefs and dukedoms, for which he substituted the smaller counties. Under the confused government of Charles's immediate successors the archbishop was the only real power in Milan. But there were two classes of difficulties in the situation, ecclesiastical and political; and their presence had a marked effect on the development of the people and the growth of the commune, which was the next stage in the history of Milan. On the one hand the archbishop was obliged to contend against the heretics or against fanatical reformers who found a following among the people; and on the other, since the archbishop was the real power in the city, the emperor, the nobles and the people each desired that he should be of their party; and to whichever party he did belong he was certain to find himself violently opposed by the other two. From these causes it sometimes happened that there were two archbishops, and therefore no central control, or no archbishop at all, or else an archbishop in exile. The chief result of these difficulties was that a spirit of independence and a capacity of judging and acting for themselves was developed in the people of Milan. The terror of the Italian invasion, in 899, further assisted the people in their progress towards freedom, for it compelled them to take arms and to fortify their city, rendering Milan more than ever independent of the feudal lords who lived in their castles in the country. The tyranny of these nobles drove the peasantry and smaller vassals to seek the protection for life and property, the equality of taxation and of justice, which could be found only inside the walled city and under the rule of the archbishop. Thus Milan grew populous, and learned to govern itself. Its inhabitants became the manufacturers, the manufacturers of foreign conquerors, but a distinct people, with a municipal life and prospects of their own. For the further growth of the commune, the action of the great archbishop, Heribert (1018–1045), the establishment of the carraocci, the development of the Milanese supremacy in Lombardy, the destruction of Lodi, Como, Pavia and other neighbouring cities, the exhibition of free spirit and power in the Lombard league, and the battle of Legnano, see the articles ITALY and LOMBARDIES. In 1157 an almost circular moat, still preserved in the inner canal or Naviglio, was constructed round the town; but in 1162 Frederick Barbarossa took and almost entirely destroyed the city, only a few churches surviving. The city with its walls was, however, rebuilt five years later by the allied cities of Bergamo, Brescia, Mantua and Verona.

The battle of Legnano, in 1174, although the Lombard cities failed to reap the fruit of their united action, fell to mutual jealousy once more, Milan internally began to grow in material prosperity. After the peace of Constance (1283) the city walls were extended; the arts flourished, each in its own quarter, under a syndic who watched the interests of the trade. The manufacture of armour was the most important industry. During the struggles with Barbarossa, when freedom seemed on the point of being destroyed, many Milanese vowed themselves, their goods and their families to the Virgin should their city come safely out of her troubles. Hence arose the powerful fraternity of the "Umiliani," who established their headquarters at the Brera, and began to develop the wool trade, and subsequently gave the first impetus to the production of silk. From this period also date the irrigation works which render the Lombard plain a fertile garden. The government of the city continued to be in the hands of a single archbishop, who, by the great power of the church, including all who possessed bread and wine of their own, a council soon found to be unmanageable owing to its size, and reduced first to 2000, then to 1500 and finally to 800 members; (b) a cedrenza or committee of 12 members, elected in the grand council, for the despatch of urgent or secret business, (c) the consuls, the executive, elected for one year, and compelled to report to the great council at the term of their office.

The bitter and well-balanced rivalry between the nobles and the people, and the endless danger to which it exposed the city
owing to the fact that the nobles were always ready to claim the protection of their feudal chief, the emperor, brought to the front two noble families as protagonists of the contending factions—the Torriani of Valsassina, and the Visconti, who derived their name from the office of delegates which they held under the archbishops. After the battle of Cortenova, in 1237, where Frederick II. defeated the Guelph army of the Milanese and captured their carroccio, Pagano della Torre rallied and saved the remnants of the Milanese. This act recommended him to popular favour, and he was called to the government of the city—but only for the distinct purpose of establishing the “catasta,” a property tax which should fall with equal incidence on every citizen. This was a democratic measure which marked the party to which the Torriani belonged and rendered them hateful to the nobility. Pagano died in 1241. His nephew Martino followed as podestà in 1256, and in 1259 as signore of Milan—the first time such a title was heard in Italy. The nobles, who had gathered round the Visconti, and who threatened to bring Ezzelino da Romano, the Ghibelline tyrant of Padua, into the city, were defeated by Martino, and 900 of their number were captured. Martino was followed by two other Torriani, Filippo his brother (1263–1265) and Napoleon his cousin (1265–1277), as lords of Milan. Napoleon dedicated himself to the task of uniting the various partisans of the Visconti and of his cousin, John of Hapsburg. But the nobles under the Visconti had been steadily gathering strength, and Napoleon was defeated at Desio in 1277. He ended his life in a wooden cage at Castel Baradello above Como.

Otto Visconti, archbishop of Milan (1262), the victor of Desio, became lord of Milan, and founded the house of Visconti, which ruled the city—except from 1302 to 1310—till 1447, giving twelve lords to Milan. Otho (1277–1295), Matteo (1310–1322), Galeazzo (1322–1328), Azzone (1328–1330), Lucchino (1339–1349), and Giovanni (1349–1354) followed in succession. Giovanni left the lordship to three nephews—Matteo, Galeazzo and Bernabò. Matteo was killed (1355) by his brothers, who divided the Milanese. Bernabò reigning in Milan (1354–1385) and Galeazzo in Pavia (1354–1378). Galeazzo left a son, Gian Galeazzo, who became sole lord of Milan by seizing and imprisoning his uncle Bernabò. It was under him that the cathedral of Milan and the Certosa of Pavia were begun. He was the first duke of Milan, having obtained that title from the emperor Wenceslaus. His son was Bernardo Maria, who reigned at Milan (1400–1412), and Filippo Maria, who reigned at Pavia (1402–1447), succeeded him. In 1412, on his brother's death, Filippo united the whole duchy under his sole rule, and attempted to carry out his father's policy of agrandizement, but without success.

Filippo was the last male of the Visconti house. At his death a republic was proclaimed, which lasted only three years. In 1450 the general Francesco Sforza, who had married Filippo's only child Bianca Visconti, became duke of Milan by right of conquest if any right. Under this duke the castle was rebuilt and the canal of the Martesana, which connects Milan with the Adda, and the Great Hospital were carried out. Francesco was followed by five of the Sforza family. His son Galeazzo Maria (1466–1476) left a son, Gian Galeazzo, a minor, whose guardian and uncle Lodovico (il Moro) usurped the duchy (1476–1500). Lodovico was captured in 1500 by Louis XII. of France, and Milan remained for twelve years under the French crown. In the partial settlement which followed the battle of Ravenna, Massimiliano Sforza, a legitimate of the emperor, was restored to the throne of Milan, and held it by the help of the Swiss till 1515, when Francis I. of France reconquered the Milanese by the battle of Marignano, and Massimiliano resigned the sovereignty for a revenue from France. This arrangement did not continue. Charles V. succeeded the emperor Maximilian, and at once disputed the possession of the Milanese with Francis. In 1522 the imperialists entered Milan and proclaimed Francesco Sforza (son of Lodovico). Francesco died in 1535, and with him ended the house of Sforza From this date till the War of the Spanish Succession (1714) Milan was a dependency of the Spanish crown. At the close of that war it was handed over to Austria; and under Austria it remained till the Napoleonic campaign of 1796. For the results of that campaign, and for the history of Italian progress towards independence, in which Milan played a prominent part by opening the revolution of 1848, with the insurrection of the Cinque Giornate (March 17–22), by which the Austrians were driven out; the reader is referred to the article ITALY. The Lombard campaign of 1859, with the battles of Solferino and Magenta, finally made Milan a part of the kingdom of Italy.

Ital. scriptores; Simonetti, Storia della Casa del敏迷; Giovanni Vasi, Vite celebri, s. v. “Torriani,” Visconti,” “Sforza,” and “Trivulzi;” Muratori, Annales d’Italia; Hallam, History of the Middle Ages; and Mediolanum (4 vols., 1861); L. Beltrami, Il Castello di Milano (Milan, 1891); L. del Mayo, Vincende militari del Castello di Milano (Milan, 1894); F. Malaguzzi Valeri, Milano, 2 vols. (Bergamo, 1906); and C. M. Ady, A History of Milan under the Sforza (1907). (H. F. B.; T. A.)

**MILANESI, GASTANO** (1813–1895), Italian scholar and writer on the history of art, was born at Siena, where he studied law, and in 1838 he obtained an appointment in the public library. In 1856 he was elected member of the Accademia della Crusca, in which capacity he took part in the compilation of its famous but still unfinished dictionary, and two years later was appointed assistant keeper of the Tuscan archives, in Florence; then he took the part of that institution in the desire to bring under one roof all the Tuscan archives, and thus to form a vast body of material on the history of Italian art, not all of which is yet published. In 1889 he became director of the archives, but retired in 1892, and died three years later. His most important publication is his edition of Vasi’s works in nine volumes, with copious and valuable notes (Florence, 1878–1888). Of his other writings the following may be mentioned: Il diario inedito di Alessandro Sessini (in the Archivio storico Italiano, 1842); Documenti per la storia dell’arte senese, 3 vols. (Siena, 1854–1866); and Discorsi sulla storia civile e artistica di Siena (Siena, 1862). He also edited a number of Italian classics. See E. Ridolfi’s article in the Nuova antologia (May 15, 1865), and A. Virgili’s article in the Atti della regia Accademia della Crusca (Florence, 1898).

**MILAN OBRENOVICH IV.** (1854–1901), king of Servia, was born on the 22nd of August 1854, at Jassy. He was the grand-nephew of the famous Milos, whose brother Jefrem (d. 1856) had a son, Miklos (1829–1861), who married Maria Katardži, a Moldavian. Milan was their son. While still very young, he lost both his parents, and was adopted by his cousin, Michael Obrenovich, who returned to Servia on the expulsion of the Karageorgeviches in 1858 and became ruling prince on the death of his father, Milosh, in 1860. During the reign of Michael young Milan was educated in Paris, at the Lyceu Louis-Grand, where he displayed considerate precocity, but he was only fourteen years of age when in 1868 his cousin was assassinated and he succeeded to the throne under a regency. In 1872 he was declared of age, and taking the reins of government into his own hands, soon manifested great intellectual power, coupled with a passionate headstrong character. Eugene Schuyler, who saw him about this time, found him “a very remarkable young man . . . singularly intelligent and well-informed.” By a careful balancing of the Austrian and Russian parties in Servia, with a judicious use of force towards the Roumanians, Milan was enabled in 1878, at the end of the Turkish War, to induce the Porte to acknowledge his independence, and was proclaimed king in 1882. (The history of his reign is told in detail under SERBIA.) Acting under Austrian influence, King Milan devoted all his energies to the improvement of means of communication and the development of natural resources, but the cost, which was unduly increased by reckless extravagance, led to proportionately heavy taxation. This, coupled with increased military service, rendered King Milan and the Austrian party most unpopular; and his political troubles were further increased by the defeat of the Servians in the war against Bulgaria, 1885–86. In 1885 (Sept.) the union of Rumelia and Bulgaria caused widespread agitation in Servia, and Milan precipitately declared war upon his kinsman Prince Alexander on the 15th of November. After
a short but decisive campaign, the Servians were utterly routed at the battles of Slivinska and Pirot, and Milan's throne was only saved by the direct intervention of Austria. Domestic difficulties now arose which rapidly assumed a political significance. In October 1875 King Milan had married Natalie, the sixteen-years-old daughter of Peter Ivanovich Ketchko, a Moldavian Boyar, who was a colonel in the Russian army, and whose wife, tulchera, was by birth Princess Sturza. A son, Alexander, was born in 1876, but the king and queen showed signs of friction. Milan was anything but a faithful husband. Queen Natalie was greatly influenced by Russian sympathies; and the couple, ill-assorted both personally and politically, separated in 1886, when the queen withdrew from the kingdom, taking with her the young prince, Alexander, afterwards king, then ten years of age. While she was residing at Wiesbaden in 1888, King Milan succeeded in recovering the crown prince, whom he undertook to educate; and in reply to the queen's remonstrances, he exerted considerable pressure upon the metropolitan, and procured a divorce, which was afterwards annulled as illegal. King Milan now seemed master of the situation, and on the 3rd of January 1889 promulgated a new constitution much more liberal than the existing one of 1869. Two months later (March 6) he suddenly abdicated in favour of his son, a step for which no satisfactory reason was assigned, and ved as a Milanesa individual violation of the constitution. Radical ministry was formed, Queen Natalie and the ex-metropolitan Michael returned to Belgrade, and Austrian influence began to give way to Russian. Fear of a revolution and of King Milan's return led to a compromise, by which in May 1891 the queen was expelled, and Milan was allowed a million francs from the civil list, on condition of not returning to Servia during his son's minority. Milan in March 1892 renounced all his rights, and even his Servian nationality. The situation altered, however, after the young King Alexander in April 1893 had effected his coup d'état and taken the reins of government into his hands. Servian politics began to grow more complicated, and Russian intrigue was rife. In January 1894 Milan suddenly appeared at Belgrade, and his son gladly availed himself of his experience and advice. On the 29th of April a royal decree reinstated Milan and Natalie, who in the meantime had become ostensibly reconciled, in their position as members of the royal family. On the 21st of June a new constitution of 1892 was restored, and Milan continued to exercise considerable influence over his son. The queen, who had been residing chiefly at Biarritz, returned to Belgrade in May 1895, after four years' absence, and was greeted by the populace with great enthusiasm. In 1897 Milan was appointed commander-in-chief of the Servian army. In this capacity he did some of the best work of his life, and his success in improving the Servian military system was very marked. His relations with the young king also remained good, and for a time it seemed as though all Russian intrigues were being checked. The good relations between father and son were interrupted, however, by the latter's marriage in July 1900. Milan violently opposed the match, and resigned his post as commander-in-chief; and the young king banished him from Servia and threw himself into the arms of Russia. Milan retired to Vienna, and there he died unexpectedly on the 11th of February 1901. Milan was an able, though headstrong man, but he lived a scandalously irregular life and was devoid of moral principle. In considering his relations with his young son, it must be remembered that in the dynastic and political condition of Servia natural feeling was inevitably subordinated in Milan to other considerations. (H. C.)

MILÁ Y FONTANALS, MANUEL (1818-1884), Spanish scholar, born at Villafranca del Panadés, near Barcelona, on the 4th of May 1818, was educated first at Barcelona, and afterwards at the university of Cervera. In 1845 he became professor of literature at the university of Barcelona, and held this post till his death at Villafranca del Panadés on the 16th of July 1884. The type of the scholarly recluses, Milá y Fontanals was almost unknown outside the walls of the university till 1859, when he was appointed president of the juegos florales at Barcelona.

On the publication of his treatise, De Los trovadores en España (1866), his merits became more generally recognized, and his monograph, De La poeta heroico-popular castellana (1873) revealed him to foreign scholars as a master of scientific method.

MILAZZO, a seaport on the north coast of Sicily, in the province of Messina, 22 m. W. of Messina by rail. Pop. (1901), 16,422. It is mainly built on the low isthmus of a peninsula, which stretches some 3 m. farther north and forms a good harbour: but the old town, which contains a castle, mainly the work of Charles V., lies on a hill above. Milazzo is the ancient Mylae, an outpost of Zancle, occupied before 648 B.C., perhaps as early as 716 B.C. (E. A. Freeman, History of Sicily, I, pp. 395, 587). It was taken by the Athenians in 426 B.C. The people of Rhegium planted here the exiles from Naxos and Catana in 495 B.C. as a counterpoise to Dionysius' foundation of Tyndaris; but Dionysius soon took it. In the bay Duillus won the first Roman naval victory over the Carthaginians (260 B.C.).

MILDENHALL, a market town in the Stowmarket parliamentary division of Suffolk, England, 76 m. N.N.E. from London by a branch of the Great Eastern railway from Cambridge. Pop. (1901), 3567. It lies on the edge of Mildenhall Fen, the great Fen district stretching northward and westward from here. The church of St Andrew has an Early English chancel with fine east window and chancel arch. The remainder is principally 15th century. It is the church of a manor with a north porch and lofty tower with fan tracery within. There is a wooden market cross of the 15th century; the manor house is a picturesque gabled building of the 17th century, and there is a modern public hall. Flour milling is an industry. The discovery of Roman remains indicates a small settlement.

MILDEW (O. Eng. meledaw or mildeaw, explained as "meal-dew," cf. Ger. Mehlibau, with more probability, as "honey-dew," Goth. melitthus, honey, cf. Lat. mel, Gr. μέλι), a popular name given to various minute fungi from their appearance, and from the sudden, dew-like manner of their occurrence. Like many other popular names of plants, it is used to denote different species which possess very small botanical affinity. The term is applied, not only to species belonging to various systematic groups, but also to such as follow different modes of life. The corn-mildew, the hop-mildew and the vine-mildew are, for example, parasitic upon living plants, and the mildews of damp linen and other materials are chiefly related to fungal rot (16,422, roten), that is, they subsist on matter which is already dead. As regards mildews in general, the conditions of life and growth are mainly suitable nutrition and dampness accompanied by a high temperature. The life history of the same species of mildew frequently covers two or more generations, and these are often passed on hosts of different kinds. In some cases again the same generation confines its attack to the same kind of host, while in others the same generation grows on various hosts (see FUNGI; HOP; and WHEAT).

MILES, NELSON APPELAND (1839-1885), American soldier, was born in Westminister, Massachusetts, on the 8th of August 1839. He was engaged in mercantile pursuits in Boston when the Civil War began, and he entered the army in September 1861 as a lieutenant in the 2nd Massachusetts volunteer infantry. He served with distinction in the Peninsular campaign, and at Antietam, Fredericksburg and Chancellorsville, where he received a wound which incapacitated him up to the opening of Grant's Virginia campaign of 1864. He had been commissioned in September 1862 colonel of the 61st New York volunteers, commanded a brigade at the Wilderness and Spottsylvania, and in May 1864, was rewarded for his gallant leadership by the grade of brigadier-general of volunteers. He fought in the Cold Harbor and Petersburg operations in 1864-65, was brevetted major-general of volunteers for his conduct at Reams Station, and at the close of the war was in temporary command of an army corps. In July 1866 he was made colonel of a regular infantry regiment, and in 1867 he was brevetted brigadier-general in the regular army for his services at Chancellorsville and major-general for his services at Spottsylvania. He was promoted to brigadier-general U.S.A. (Dec. 1880), and to be
MILETUS— MILFORD

443

major-general (April 1896), and in 1895 succeeded General John McA. Schofield as commanding general of the United States army. He was conspicuously successful (1867-1886) in dealing with Indian outbreaks, fighting the Cheyenne, Kiowa and Comanche on Llano Estacado (1872) and the Sioux in Montana (1876), capturing the Nez Percés under Chief Joseph (1877), and defeating the Chiricahua Apaches under Geronimo (1886), and he commanded the United States troops sent to Chicago during the railway riots in 1894. He was in nominal direction of military operations during the war with Spain in 1898, though his personal share of the operations was confined to directing the almost unopposed Porto Rico expedition. He was raised to the rank of lieutenant-general in June 1900, and retired from active service in August 1903. In 1905-1906 he was adjutant-general and chief-of-staff under Governor William L. Douglass in Massachusetts. He wrote Personal Recollections (1896), Military Europe (1898) and Observations Abroad (1890).

MILETUS (mod. Palaia), an ancient city of Asia Minor, on the southern shore of the Latmic Gulf near the mouth of the Maaende. Before the Ionic migration it was inhabited by Carians (c. 650 B.C.); Herodotus (i. 146), and pottery, found by Th. Wiegand on the spot. Miletus was then the site of the ancient Ionian settlement with the Aegean world, in the latest Minoan age. The Greek settlers from Pylos under Neles are said to have massacred all the men in the old city, and built for themselves a new one on the coast. Miletus occupied a very favourable situation at the mouth of the rich valley of the Maaender, and was the natural outlet for the trade of southern Phrygia (Hipponax, Fr. 45). It had four harbours, one of considerable size, and its power extended inland for some distance up the valley of the Maaender, and along the coast to the south, where it founded the city of Iassus. Its enterprise extended to Egypt, where it had much to do with the settlement of Naucratites (q.v.). Very little "Naucratitai" pottery, however, was found on the site by Wiegand, and only in the Athena temple. The Black Sea trade, however, was the greatest source of wealth to the Ionian cities. Miletus, like the rest, turned its attention chiefly to the north, and succeeded in almost monopolizing the traffic. Along the Hellespont, the Propontis and the Black Sea coasts, it founded more than sixty cities—among them Abydus, Cyzicus, Sinope, Dascyria, Panticapaeum and Olbia. All these cities were founded before the middle of the 7th century; and before 500 B.C. Miletus was decidedly the greatest Greek city. During the time when the enterprise of the seafaring population raised Miletus to such power and wealth nothing is known of its internal history, though the analogy of all Greek cities, and some casual statements in later writers, suggest that the usual struggles took place between oligarchy and democracy, and that tyrants sometimes raised themselves to supreme power. Miletus was equally distinguished at this early time as a seat of literature. The Ionian epic and lyric poetry indeed had its home farther north; philosophy and history were more akin to the practical race of Miletus, and Thales, Anaximander, Anaximenes and Hecataeus all belonged to this city. The poet Timotheos and the famous Aspasia were also natives. The three Ionian cities of Caria—Miletus, Myus and Priene—spoke a peculiar dialect of Ionic. The Mermaid kings of Lydia found in Miletus their strongest adversary. War was carried on for many years, with Alyattes III. concluded a peace with Thrasybulus, tyrant of Miletus, afterwards seem to have acknowledged peaceably the rule of Croesus. On the Persian conquest Miletus passed under a new master; it headed the Ionian revolt of 500 B.C., and was taken by storm after the battle of Lade (see IONIA). Darius massacred most of the inhabitants, transported the rest to Ampe at the mouth of the Tigre, and gave up the city to the Carians. This disaster was long remembered in Greece and made the theme of a tragedy by Phrynichus. Henceforth the history of Miletus has no special interest. It revived indeed when the Persians were expelled from the coast in 470 B.C., became a member of the Delian League (q.v.), revolted to Sparta in 412, passed into Carian hands, and opposed Alexander on his southward march, succumbing only to a siege in form (334 B.C.). It was a town of commercial importance throughout the Graeco-Roman period, and received special attention from Trajan. Its harbour protected by Lade and the other Tragassaeans islands, were gradually silted up by the Maaender, and Lade now a hill some miles from the coast. Ephesus took its place as the great Ionian harbour in Hellenistic and Roman times. Miletus became the seat of a Christian bishopric and was strengthened by a Byzantine castle (κάστρον τῶν Παλαιων) built above the town; but its decay was inevitable, and its site is now a marsh.

Since 1890 Miletus has been the scene of extensive excavations directed by Dr Th. Wiegand for the Berlin Academy. The ruins lie about the base of a hillock projecting north-east to a bend of the Maaender. On the north is a well-preserved theatre of Roman date, with the site of an earlier Greek theatre in front of it had 54 rows of seats. It was as large as any theatre in Asia Minor, and is still imposing, the auditorium, though deprived of its upper ranks and colonnade, rising nearly 100 ft. Cyran of Ancona sold "The Auspices building as practically complete in his day (1465). The front is over 150 yds. long. East of this was the ancient north harbour, now silted up, and on the hillside above it stood a large heroen of Hellenistic time remarkable for being, like the temple of the cross at Ephesus, one, the foundations of which have been described with the heroen of Artemis, once richly adorned with reliefs. The Theatre of Dionysus lies beyond this again. A straight street leads south-west from the north harbour to the Didyma Gate in the wall, which runs across the neck of the peninsula and was rebuilt by Trajan, when he understood, of the level and greater grandeur of the city; and streets cross this at right angles in the geometric Hellenistic manner. A Sacred Way lined with tombs, led to Didyma. Two temples have been discovered by Dr Wiegand, one, on the south-east, the sanctuary of Apollo Daphnius with triple colonade around the temple, and enasuring a court with central tripod. This seems to have been the chief temple of the city and the place where public records, treaties, &c., were engraven. The other temple, an archaic sanctuan of the Maaender, lies west of the agora.

(D. G. H.)

MILFORD, a township of New Haven county, Connecticut, U.S.A., on Long Island Sound, separated from the township of Stratford on the W. by the Housatonic river, and about 10 m. S.W. of New Haven. Pop. (1890), 3811; (1900), 3783, including 514 foreign-born and 173 negroes; (1910), 4366. Area, about 16 sq. m. Milford is served by the New York, New Haven & Hartford railroad, and by an electric line connecting with Bridgeport and New Haven. Within its borders are various popular beaches, including Woodmont (incorporated as a borough in 1903), Pond Point, Bay View, Fort Trumbull Beach (where a fortification, named Fort Trumbull, was erected in 1776), Myrtle Beach, Meadow's End, Walnut Beach and Milford Point. The township is traversed by the Wepawaug river, which here empties into the Sound. Milford is a typical old New England town, and many of the permanent inhabitants are descendants from the first settlers. The burying-ground includes the tomb of Robert Treat (1622-1710), commander of the Connecticut troops in King Philip's War, leader of the company that founded Newark, New Jersey, governor of Connecticut (from 1683 to 1693), and by a warrant of the charter was demanded by Governor Andros in 1686-1687, and deputy-governor in 1696-1698 and 1698-1708; and also that of Jonathan Law (1674-1751), governor of Connecticut from 1742 to 1751. Spanning the Wepawaug river near a gorge and not far from its mouth is a granite bridge and tower, built, as a memorial to the first settlers, in 1889, in connexion with the celebration of the 250th anniversary of the founding of the town. Milford has a beautiful green of about four acres, containing a soldiers' monument. It has also the Taylor Library (founded in 1804), and along the Sound are many summer residences. Named after Milford, England, it was founded in 1639 by Rev. Peter Prudden and his followers from New Haven and Wethersfield. The land was purchased from the Indians for 6 coats, 10 blankets, 1 kettle, 12 hatchets, 12 hoes.
24 knives and 12 small mirrors. A “church-state” was immediately organized after the model of that of New Haven, but two or three years later the town bestowed suffrage on six of its inhabitants who were not church members. These citizens were an obstacle to the town’s admission to the New Haven Jurisdiction, which was formed in 1643, but in the following year a compromise was effected and Milford was admitted on condition that, in the future, suffrage should be granted only to church members and that none of the objectionable six should be elected to any office of the Jurisdiction. In 1664 Milford, with the other members of the Jurisdiction, was absorbed by Connecticut; this caused considerable dissatisfaction and some of the inhabitants under the lead of Robert Treat removed to New Jersey and assisted in the founding of Newark. The regicides Whalley and Goffe were concealed in Milford from 1661 to 1664.

MILFORD, a township of Worcester county, Massachusetts, U.S.A., about 16 m. S.E. of Worcester. Pop. (1890), 7890; (1900) 11,376, of whom 3342 were foreign-born; (1910 census) 13,055. Within its area of about 15 sq. m. are a large rural population and the village of Milford, on the Charles river, about 33 m. S.W. of Boston, served by the Boston & Albany, the New York, New Haven & Hartford and the Grafton & Upton railways (the last named having its passenger department operated by electricity and its freight by steam, and connecting Milford with North Grafton), and by inter-urban electric lines. The village has a memorial hall, housing the public library, and in the township there is an excellent hospital, the gift of Eben. S. Draper. The village is a shipping point for an agricultural and manufacturing district. In 1905 the value of the township’s factory products was $3,390,594 (32-8% more than in 1900). The most important manufactures are boots and shoes; the industry was established in 1765, and for many years the special product was brogans for Southern negroes. In 1900 there were 667 establishments and 2792 hands engaged in the industry, and the output was valued at $962,588. Granite quarries and the granite works (north and north-east of the village) yield granite for use in the building of the eastern States. Granite is the typical stone of an area reaching into Rhode Island south of the southern boundary of Providence county; it is a biotite granite of post-Cambrian age, generally pinkish-gray in color (owing to the large proportion of feldspar among its constituents), and is widely used for building purposes.

The township was the east precinct of Mendon until 1780, when it was incorporated; in 1835 parts of Holliston and Hopkinton were annexed; in 1886 a part was separated as Hopedale.

MILFORD HAVEN, a market town, seaport, urban district and contributory parliamentary borough of Pembrokeshire, Wales, situated on the north shore of the celebrated harbour of the same name. Pop. (1901), 5102, including the adjacent village of Hakin. Milford Haven is the terminus of a branch-line of the South Wales section of the Great Western railway. The town possesses a pier and important dock accommodation, including a graving-dock 600 ft. long, and is the centre of a valuable and increasing fishing industry. The promenade of Hamilton Terrace commands a fine view of the broad expanse of the Haven with its various towns and forts.

The present town of Milford Haven, originally a hamlet in the parish of Steynton, is of modern growth, and was first called into existence by the exertions of the Hon. R. F. Greville, nephew of Sir William Hamilton, who in 1790 laid out a town on this spot, the advantages of which as a convenient port for the Irish traffic he clearly recognized. In the opening years of the 19th century a royal dockyard was established here, but in 1814 dockyard and arsenal were removed to Paterchurch near Pembroke. The growth of the town was further checked twenty-two years later by the development of Neyland, or New Milford, further east on the Haven, whither the Irish packet service was transferred; but towards the close of the 19th century the town recovered much of its former prosperity. The importance of the place is wholly due to its excellent situation on the splendid land-locked harbour, which is here 2 m. broad.

Milford Haven itself, designated by the Welsh Aberdaugledddau, as the estuary of the united East and West Cleddy rivers, has played an important part on several occasions in the course of history. Throughout Plantaganet times it bore the chief point of embarkation for Ireland. It was from Milford Haven that Henry II. set sail for the conquest of Ireland in 1172, and to this harbour he made his return journey. In 1396 Richard II. landed at Milford Haven from Ireland, shortly before his surrender to Henry of Lancaster, afterwards Henry IV., in whose reign a French fleet with 12,000 men on board sailed to the Haven and disembarked with the object of assisting the rebellion of Owen Glendower. In 1485 Henry, earl of Richmond, disembarked here on his return from France, and was welcomed on landing by Sir Rhys ap Thomas and much of the chivalry of Wales. In 1588 the leading persons of Pembrokeshire, with Bishop Anthony Rod of St David’s at their head, petitioned Queen Elizabeth to fortify the Haven against the projected Spanish invasion, upon which the block-houses of Dale and Nangle at either side of the mouth of the harbour were accordingly erected. During the 17th century numerous forts have been constructed for the protection of the Haven and of the royal dockyard at Pembroke Dock.

MILICZ, or MILITZ (d. 1374), Bohemian divine, was the most influential among those preachers and writers in Moravia and Bohemia who, during the 14th century, in a certain sense paved the way for the reforming activity of Huss. The date of his birth is not known, but he was in holy orders in 1350, in 1360 was attached to the court of the emperor Charles IV., whom he accompanied into Germany in that year, and about the same time also held a canonry in the cathedral of Prague along with the dignity of archdeacon. About 1363 he resigned all his appointments that he might become a preacher pure and simple; he gave up his house, and (an innovation) the laity in their native Czech, or in German which he learnt for the purpose. He was conspicuous for his apostolic poverty and soon roused the enmity of the mendicant friars. The success of his labours made itself apparent in the way in which he transformed the notorious “Benatki” street of Prague into a benevolent institution, “Jerusalem.” As he viewed the evils inside and outside the church in the light of Scripture, the conviction grew in his mind that the “abomination of desolation” was now seen in the temple of God, and that antichrist had come, and in 1367 he went to Rome (where Urban V. was expected from Avignon) to expound these views. He affixed to the gate of St Peter’s a placard announcing his sermon, but before he could deliver it was thrown into prison by the Inquisition. Urban, however, on his arrival, ordered his release, whereupon he returned to Prague, and from 1369 to 1372 preached daily in the Teyn of St Peter’s. In the latter year the clergy of the diocese complained of him in twelve articles to the papal court at Avignon, whither he was summoned in Lent 1374, and where he died in the same year, not long after being declared innocent and authorized to preach before the assembly of cardinals. He was the author of a Libellus de Antichristo, written in prison at Rome, a series of Postilla and Lectiones quadragesimales in Latin, and a similar series of Postils (devotional tracts) in Czech.

MILITARY FRONTIER (Ger. Militärgrenze, Slav. Granicita), a narrow strip of Austrian-Hungarian territory stretching along the borders of Turkey, which had for centuries a peculiar military organization, and from 1849 to 1873 constituted a crown-land. As a separate division of the monarchy it owed its existence to the necessity of maintaining during the 16th and 17th centuries a strong line of defence against the invasions of the Turks, and may be said to have had its origin with the establishment of the crown-land by Matthias Corvinus and the introduction of Uakoks (q.v.) into Croatia. By the close of the 17th century there were three frontier “generales”—Carlstadt, Warasdin and Petrinia
forces to which it was applied, in a period of war only. Troops were raised for a particular service, and were disbanded upon the cessation of hostilities. The crown, of its mere prerogative, made laws known as Articles of War, for the government and discipline of the troops while thus embodied and serving. Except for the punishment of desertion, which offence was made a felony by statute in the reign of Henry VI., these ordinances or Articles of War remained almost the sole authority for the enforcement of discipline until 1689, when the first Mutiny Act was passed and the military forces of the crown were brought under the direct control of parliament. Even the Parliamentary forces in the time of Charles I. and Cromwell were governed, not by an act of the legislature, but by articles of war similar to those issued by the king and authorized by an ordinance of the Lords and Commons, exercising in that respect the sovereign prerogative. This power of law-making by prerogative was, however, held to be applicable during a state of actual war only, and attempts to exercise it in time of peace were ineffectual. Subject to this limitation it existed for considerably more than a century after the passing of the first Mutiny Act. From 1689 to 1803, although in peace time the Mutiny Act was occasionally suffered to expire, a statutory definition given to the term and its operation established in the colonies and elsewhere beyond the seas in the same manner as those made by prerogative operated in time of war. In 1715, in consequence of the rebellion, this power was created in respect of the forces in the kingdom. But these enactments were apart from and in no respect affected the principle acknowledged all this time—that the crown of its mere prerogative could make laws for the government of the army in foreign countries in time of war. The Mutiny Act of 1803 effected a great constitutional change in this respect: the power of the crown to make any Articles of War became altogether statutory, and the prerogative merged in the act of parliament. So matters remained till the year 1879, when the last Mutiny Act was passed and the last Articles of War were promulgated. The Mutiny Act legislated for offences in respect of which death or penal servitude could be awarded, and the Articles of War, while repeating those provisions of the act, constituted the direct authority for dealing with offences for which imprisonment was the maximum punishment as well as with many matters relating to trial and procedure. The act and the articles were found not to harmonize in all respects. Their general amendment, the Royal London and other municipal authorities are supreme; and whilst they can call upon the civil power to act in concert with them, the military authority is final. This is a brief summary of the system of military law that prevails in most countries of the continent. The cardinal point of difference between the British and the continental systems lies in the fact that in the United Kingdom the soldier is not only a soldier, but a citizen also; and although he may be tried for civil offences by a military tribunal, the power is not exercised in all cases. Thus treason, treason-felony, murder, manslaughter, rape, are brought before a civil court in times of peace, if the offence is committed in the United Kingdom, or if it is committed anywhere else in the king's dominions, except Gibraltar, within a hundred miles from a place where the offender can be tried by a civil court. Minor civil offences, when not committed within military lines, or when the person affected by the offence is a civilian, or when it is a case for a jury, or where intricate questions of law may arise, may also be brought before a civil tribunal. But an offence, of whatever nature, committed on active service would be brought before a military tribunal.

The military law of England in early times existed, like the

1 By 1848 the following had come to be the division of the Military Frontier: (1) The Carlsbad (Carlowate), Warsasind and Banal Generality; corresponding to the original three generations. (2) The Slavonian Generality; (district of Mitrovica). (3) The Banal Generality; south east of Temesvar, and (4) The Transylvanian Generality. Twelve towns, known as "military communities," had communal constitutions not unlike those of the free towns of Hungary-Carlapago, Zengg, Petraina, Kostajnica, Belvar, Ivanic, Brod, Peterwardein, Carlowitz, Semlin, Pancsova and Weisskirchen.

1 MILITARY LAW
an authority derived from and defined and limited by statute. Although in 1879 the power of making Articles of War became in effect altogether inoperative, the sovereign was empowered to make rules of procedure having the force of law, which regulate the administration of the act in many matters formerly dealt with by the Articles of War. These rules, however, must not be inconsistent with the provisions of the Army Act itself, and must be laid before parliament immediately after they are made. Thus in 1879 the government and discipline of the army became for the first time completely subject either to the direct action or the close supervision of parliament.

A further notable change took place at the same time. The Mutiny Act had been brought into force on each occasion for one year only, in compliance with the constitutional theory that the maintenance of a standing army in time of peace, unless with the consent of parliament, is against law. Each session therefore the text of the act had to be passed through both Houses clause by clause and line by line. The Army Act, on the other hand, is a fixed permanent code. But constitutional traditions are fully respected by the insertion in it of a section providing that it shall come into force only by virtue of an annual act of parliament. This annual act recites the illegality of a standing army in time of peace unless with the consent of parliament, and the necessity nevertheless of maintaining a certain number of land forces (exclusive of those serving in India) and a body of royal marine forces on shore, and of keeping them in exact discipline, and it brings into force the Army Act for one year.

Military law is thus chiefly to be found in the Army Act and the rules of procedure made thereunder, the Militia Acts, the Reserve Forces Acts and the Volunteer Acts, together with certain acts relating to the yeomanry, the Territorial and Reserve Forces Act 1907, and various royal warrants and regulations. In the Army (Annual) Act 1906 important amendments were made to the Army Act for the purpose of preventing soldiers convicted of offences against discipline under the act, and not discharged with ignominy, being subjected to the stigma attaching to imprisonment, termed detention, the places in which soldiers undergo detention being termed detention barracks. The change, while principally one of nomenclature, removed an undoubted grievance. The Army Act itself, is, however, the chief authority. Although the complaint has been sometimes made, and not without a certain amount of reason, that it does not accomplish much that it might in point of brevity, simplicity and clearness of expression, it is a very comprehensive piece of legislation, and shows some distinct improvements upon the old Mutiny Acts and Articles of War.

When a person subject to military law commits an offence he is taken into military custody, which means either arrest in his own quarters or confinement. He must without unnecessary delay be brought before his commanding officer, who upon investigating the case may dismiss the charge. If in his discretion he shall find the charge not to be proven, he may take steps to bring the offender before a court martial. Where the offender is not an officer he may dispose of the case summarily, the limit of his power in this respect being seven days' imprisonment with hard labour, a fine not exceeding 10s. for drunkenness, certain deductions from pay, confinement to barracks for twenty-eight days, this involving severe extra drills, deprivations and other minor punishments. Where the offence is absence without leave for a period exceeding seven days, the commanding officer may award a day's imprisonment in respect of each day of such absence up to twenty-one. It is only in the case of the imprisonment exceeding seven days that the evidence before the commanding officer is taken on oath, and then only in the event of the accused so desiring it. The commanding officer is enjoined by regulation not to punish summarily the more serious kind of offences, but his legal jurisdiction in this respect is without limit as regards any soldier brought before him, and when he has dealt summarily with a case the accused is free from any other liability in respect of the offence thus disposed of. In any instance where the commanding officer has summarily awarded imprisonment, fine and deduction from pay, the accused may claim a district court martial instead of submitting to the award.

Ordinary courts martial are of three kinds, viz. (1) a regimental court martial, usually convened and confirmed by the commanding officer of the regiment or detachment, presided over by an officer not under the rank of captain, composed of at least three officers of the regiment or detachment with not less than one year's service, and having a maximum power of punishment of forty-two days' detention; (2) a district court martial, usually convened by a general officer having authority to do so, consisting of not less than three officers, each with not less than two years' service, and having a maximum power of punishment of two years' imprisonment; (3) a general court martial, the only tribunal having authority to try a commissioned officer, and with a power of punishment extending to death or penal servitude, for offences for which these penalties are authorized by statute; it consists of not less than nine officers in the United Kingdom, India, Malta and Gibraltar and of five elsewhere, each of whom must have had over three years' service, five being not under the rank of captain. There is another kind of tribunal, viz. a field general court martial. It is convened (1) by any officer in command of a detachment or portion of troops beyond the seas when not on active service, or by any officer in immediate command of a body of forces on active service where it appears to him on complaint or otherwise that a person subject to military law has committed an offence. The officer must be satisfied that it is not practicable, with due regard to the public service, to try the person by an ordinary court martial. The quorum of the court is three, if consistent with military exigencies, and each member must have held a commission for not less than a year. The quorum may be reduced when the public service requires it. The procedure of ordinary courts martial is observed as far as possible, and the proceedings always should be in writing when possible. But in the circumstances in which these courts are assembled, it is not always possible to make the usual formal technical tribunals, although the broad principles are not violated. The evidence on a field general court martial is taken on oath. The prisoner may cross-examine the witnesses for the prosecution, and may call any available witnesses for his defence. The prisoner is allowed to address the court in his own defence.

The Army Act prescribes the maximum punishment which may be inflicted in respect of each offence. That of death is incurred by various acts of treachery or cowardice before the enemy, or by, when on active service, interfering with or impeding authority, lessening or contumaciously breaking out of order, being drunk on a post, plundering or committing an offence against the person or property of an inhabitant, intentionally causing false alarms, or desERTING. Whether upon active service of not, a soldier also becomes liable to the punishment of death who mutinies or incites to or joins in or conspires at a mutiny, who uses or offers violence to or defiantly disobeys the lawful command of his superior officer when in the execution of his office. Penal servitude is the maximum punishment inflicted for any irregularities upon active service not distinctly of a treacherous or wilfully injurious character, for using or offering violence or insubordinate language to a superior, or disobeying a lawful command when upon active service. The maximum punishment for desertion is five years' penal servitude. For the first offence of desertion or fraudulent enlistment (i.e., enlistment by one who already belongs to the service), certain embezlements of public property, willfully releasing without authority a prisoner from a court martial, continuing or attempting to commit an act of rudeness or privacy, being discharged from the service with disgrace without disclosing the circumstances of such discharge, or any other offence which by the ordinary criminal law of England is punishable with penal servitude. In respect of each of the two years the maximum punishment for minor forms and degrees of those offences which if committed upon active service would involve death or penal servitude, such as using or offering violence or insubordinate language to a superior, or disobeying a lawful command, the following acts of desertion or of leaving an escort, breaking out of barracks, neglect of orders, a first offence of desertion or attempted desertion or aiding or conniving at desertion, or of fraudulent enlistment, absence without leave, failure to appear at parade, going beyond prescribed bounds, absence from school, malingering or producing disease or infirmity, maiming with intent to render a soldier unfit for service, an act of a fraudulent nature, disgraceful conduct of a cruel, indelicate or unnatural kind, drunkenness, releasing a prisoner without proper authority or
allowing him to escape, being concerned in the unreasonable detention of a person awaiting trial, escaping or attempting to escape from lawful custody, contriving or abetting or procuring any horse or other animal to escape or for a fraudulent purpose in public documents, making a false accusation against an officer or soldier, or making a false confession of desertion or fraudulent enlistment, or a false statement in respect of desertion. An officer, however, who is in the civil law, is subordinate to court martial or contempt of such court, giving false evidence on oath, any offence specified in relation to billeting or the impression of carriages, making a false answer to a question put upon attestation, or the fraudulent representation of the usual dialogues regarding the sovereign, disclosing any circumstance relating to the numbers, position, movements or other circumstances of any part of His Majesty’s forces so as to produce injuries to His Majesty’s service, fighting or being concerned in or conspiring at arms, or acting in such a manner as to be considered as a contempt of court martial, and sometimes at a district court, a judge advocate general officiates, his functions being very much those of a legal assessor to the court. He advises upon all questions of law, and sets up the evidence just as a judge would in his court. When the party pleads guilty the court finds a verdict accordingly, reads the summary of evidence, hears any statement in mitigation of punishment, and takes evidence as to character and previous conduct to pass sentence. The sentence is that of the majority of the court, except where death is awarded, when two-thirds of the members in the case of a general court martial and the whole in that of a field general court martial must concur. When an acquittal is given all the charges take place the verdict is expressed as a sentence.

An officer may also be sentenced to forfeiture of seniority in rank and to reprimand or severe reprimand. A non-commissioned officer may be sentenced to reprimand or severe reprimand, or to be discharged from the service. An officer may be sentenced to a fine, or to a period of confinement or imprisonment, or to be discharged from the service. An officer may be sentenced to imprisonment, or to be discharged from the service.

Precedents of the military law are liable to be tried by court martial for offences which committed in England would be punishable by the ordinary law, and to suffer either the punishment prescribed by the ordinary criminal law or the military law, as the case may be. The power of a court martial to punish is the last resort of good order and military discipline. The effect of the latter alternative is that for many minor offences for which a civilian is liable to a short term of imprisonment, or perhaps only to a fine, a soldier may be punished by imprisonment in the prison of the fortress, or by discharge from the service. The effect of the former alternative is that for such minor offences a soldier may be discharged from the service.

himself make inquiry. But now, whenever any inquiry affects the character or military reputation of an officer or soldier, full opportunity must be given him of being present at the inquiry and of giving any evidence or making any statement. One or more examining adverse witnesses, or producing depositions, on his own behalf. Evidence may now be ordered to be taken on oath if the assembling officer thinks the case requires it. No proceedings of a court of inquiry, no confession, statement or answer, is admissible in a court martial. But an officer or soldier tried by court martial in respect of matter which has been the subject of a court of inquiry is entitled to a copy of the proceedings on the payment of the cost of the copy. The finding and sentence are only valid after confirmation by the proper military authority. A sentence of death or penal servitude can only be confirmed by the general or field officer in command of the forces with which the prisoner is present. The rule which allows the prisoner and his wife to tender their evidence on oath under the Criminal Evidence Act 1888 as regards evidence is applicable to field general courts martial. It is useful to note that the Army Act, sec. 70, enables His Majesty to make new provisions under the hand of a secretary of state for, amongst other things, the assembly and the procedure of courts of inquiry. The power to make changes by Army Order is only limited by the principle that the rules must not be contrary to or inconsistent with the act.

In an authoritative report published by the Norwegian government, and prepared by trained Norwegian lawyer who visited the various countries, the systems of twenty-two states are reviewed. The earliest military law still in force is found in Norway and Denmark, and dates from 1881, while England and Sweden date from 1883. Sweden has a military penal code, and England is ruled by the Army Act. There are two kinds of military courts of first instance: (1) those belonging to separate military bodies, such as divisions, brigades, regiments; (2) those having jurisdiction in a certain territory, and their seat determined. In times of war the courts must follow the military bodies. In Bavaria and Switzerland a military jury is attached to a court martial. In several states "auditors," i.e. judicial guides, are attached to courts martial. In some a military jurisconsult (lawyer) is attached as judge, always a fixed post. This obtains in Sweden, Finland, Austria-Hungary, Switzerland and Portugal. In Norway, Denmark, Sweden, Finland, Belgium, Great Britain, Germany, Austria, United States, Spain, Wurttemberg, Aosta, Switzerland the presiding officer is chosen for a special trial. In other states the military judge is appointed for a certain term, usually six to nine years. The term of judges required on military courts on the continent differs. Seven judges sit in Belgium, Holland, France, Spain, Portugal, Greece, Turkey and Wurttemberg; three only, in cases of ordinary offences committed by non-commissioned officers and soldiers in Switzerland, Russia, the United Kingdom, United States and Bavaria. In grave cases in the United Kingdom five to nine sit, nine in Russia, five to thirteen in the United States. In Norway and Denmark the court is of thirteen up to twenty-five, unless replaced by a commission and a military lawyer.

In Norway, Denmark, Sweden, Finland, and Bavaria and other places in Germany, special summary courts martial are held when necessary. Certain forms and legal guarantees are then dispensed with. Such are held in Belgium and Holland "in a town or place of state siege." La Prévôté is a special court of a judge assisted by a registrar, for vagabonds, servants, sutlers, and with a very limited competence over soldiers who have committed petty offence, held in time of war in France, Rumania and Greece.

The United Kingdom has a summary court martial when the regular court martial cannot be held without injuring the military service. In the United States there are the "field officers' court martial" and "military commission," consisting of three officers. The second is for judging spies and some other matters that escape the jurisdiction of the regular courts martial.

A special military tribunal in Germany judges the officials attached to the army. Courts of honour exist in Russia, Germany, Bavaria, Wurttemberg, Austria-Hungary and Spain. Great Britain and the United States have the system of a "court of inquiry." This was only a commission of inquiry, but it is now public, the accused is present, and the witnesses are sworn.

Soldiers not on active service, says the Swedish report, should be answerable for infractions of common law under the jurisdiction of the civil courts. All infractions of military order or discipline committed by soldiers, whether on active service or no, should be judged by military courts. In time of war, it is equally admitted, military courts must judge all offences, even offences at common law, committed by soldiers forming part of an army on campaign. The difference lies in regard to offences committed in time of peace. Sweden, Great Britain, France, Italy and the United States, as a general rule, place offences against the common law (infractions de droit commun) in time of peace under the jurisdiction of the civil courts. In the United States offences against good order, in Great Britain personal offences (such as drunkenness), are judged by civil courts of inquiry. The principle is that soldiers, even in time of peace, if on actual service are judged by courts martial. In the case of complicity between a soldier and a civilian, sometimes one is judged by a military and the other by a civil court (in Germany, Switzerland and Spain), sometimes both by a military court (Belgium, Italy, Servia, Rumania and Greece); sometimes it depends on the nature of the crime—In the United Kingdom, United States, Sweden, Finland, Holland and Portugal. In Norway a mixed tribunal judges them.

The procedure in military courts differs according to the countries. In some systems (a) the examination and preparation of evidence are confided to a juge d'instruction; (b) in other systems they are confided to a special commission of inquiry; (c) again, in other places they are left to the court martial itself which will judge the case. The United Kingdom and the United States follow the last plan. There is no preparatory examination in these two countries. A commission of inquiry for the preparation of evidence is held in Norway, Denmark, Germany, Wurttemberg, Austria, Russia, the United States and Spain. An auditor directs these courts of inquiry. In Russia an officer acts as juge d'instruction; in grave cases he must be a military jurisconsult. In Italy, Spain, Rumania, Greece and Turkey an officer acts as juge d'instruction.

The proceedings before a court martial are usually public, except in the case of matters that offend morality, compromise public order, or where publicity is considered injurious to the interests of the service (cases of discipline, discharge, discharge of the accused). The auditor directs the court of inquiry fills these offices (except in cases of small importance in Germany and Wurttemberg). In other states there is a special office of public prosecutor. In Spain, Portugal, Rumania, Germany, Austria (infractions of state), Belgium, Switzerland and Italy he is a military lawyer. In these countries the accused has the right to choose a counsel, or one is assigned him. In the United Kingdom and the United States, when the accused is the direction of the case is put in the hands of a judge advocate. In the United States the judge advocate is the public prosecutor.

There is no superior tribunal to which to appeal in Denmark, Great Britain, Austria, Belgium, and Switzerland. In all cases are sent to the auditor-general, who can annul if there is error in form, and send back the case to be tried anew. In Great Britain and the United States judgment in ordinary cases must be confirmed by the commanding officer by whose order the case was tried. He can also quash the sentence. In certain cases of great gravity it must go to the head of the state, after passing the revision of the judge advocate, who in Great Britain is the constitutional advisor of the crown as regards courts martial from the view of legality. There is also in these two countries a special revision of judgments in the judge advocate general's office. This revisional power is the safeguard of military justice, as all decisions are reviewed, and if any illegality is pointed out the proceedings are consequently quashed. The effect of this disapproval is not merely to annul the
proceedings, but it also prevents the accruing of any disability or forfeiture. The British judge advocate's office has been much strengthened. It now consists of: (1) The judge advocate general (one of H.M. judges); (2) a deputy judge advocate general, who is a trained lawyer; (3) an advocate general; (4) a military officer of the rank of colonel who has been called to the bar; (5) in South Africa (since 1899, and on a five-years' appointment from 1902) a colonel who has been called to the bar.

In Austria-Hungary the sentence is lightened by the commanding officer. It can also be referred for trial by a superior court if it appears to him too light. In Spain all judgments have to be confirmed, and if confirmation is refused, it is carried before the supreme court of the navy and army. The condemning has no power of appeal himself, but all cases of death or life sentences go before the supreme court of the navy and army. Russia only requires the confirmation by the commanding officer. In Italy condemned prisoners in time of peace can demand a court of revision, composed of a general and four superior officers. In time of war the court may be composed of three.

Certain forms of punishment, in all countries but the United States, can be given by the superior officer, without judicial intervention, for small purely military offences, where a summary procedure is required. The offender, if he prefers, may be carried before court-martial. The punishment is immediately carried into force, but the person punished can complain to higher military authority. In that case, if the complaint is not admitted, the punishment is enhanced. The common punishment is confinement in departmental confinement to barracks, arrests and prison. Certain special punishments obtain in certain countries—for instance, imprisonment in Turkey may be accompanied by a bread-and-water diet; and officers in Finland and Russia may be deprived of the right to go home. In 1890 France took steps to abolish courts-martial in time of peace. All common law offences to be judged by the ordinary courts, and breaches of military discipline such as rebellion, insubordination, desertion, and the like by mixed courts composed of civil and military magistrates.

MILITIA

(Fr. milice, Ger. Milis, from Lat. miles, soldier, militia, military service), a term used generally for organized military forces which are not professional in character and not permanently embodied. All ancient armies, with the exception of the personal guards of their leaders, were militias or national levies, remaining under arms for the war or the campaign and returning to their ordinary occupations at the close of each military episode. Militias such as those of the Greek city-states and that of Rome were of course highly trained to the use of arms; so were the barbarian "nations in arms"; which overcame the professional Roman armies of the Empire; and although in the Eastern Empire these new fighting elements were absorbed into a fully organized regular army, in the West the tribal militia system gradually developed into feudalism. The noble and the free man spent the greater part of their lives in the field and devoted themselves from their youth to the cult of arms, but the feudal tenantry, who were bound to give forty days' war service and no more, and the burghers who, somewhat later in the history of civilization, formed the efficient garrisons of the walled towns were true militias. The English Yeomanry indeed almost ruled the battlefield.

In the 15th century the introduction of firearms began to weigh down the balance in favour of the professional soldier. Artillery was always the arm of the specialist. The development of infantry, "fire-power," with the early arquebus and musket, called for the highest skill and steadiness in the individual soldier, and cavalry too adopted the new weapon in the form of long and expensive wheel-lock pistols. In the new military organization there was no place for the unprofessional soldier. The role of the unprofessional combatant, generally speaking, was terminated by the advent of the horse-borne soldier and the enemy, cutting off stragglers, and plundering convoys. Towards the end of the first civil war in England (1645) the country-folk banded together to impose a peace on the two warring armies, but their menace was without effect, and they were easily disarmed by Fairfax and Cromwell, who did not even trouble to hold them as prisoners. The calling out of the arrière ban of Franque-Comté in 1675 displayed its ludicrous inefficiency, and thereafter in France, which set the fashion to

Europe in all military matters, the "provincial militia," which Louvois and Barbezieux raised in place of the discredited arrière ban, was employed partly to find drafts for and partly to augment the regular army.

When a first line army was large enough to absorb the fighting strength of the country there was neither room nor need for a true militia force. This was the case with France under Napoleon's régime, but things were different elsewhere. In Great Britain the county militia (whose special history is briefly sketched below) was permanently embodied during the greater part of the Napoleonic Wars. Destitute as it was of technical and administrative services, of higher staffs and organization, and even of cavalry, this militia was a regular army in all but name. Combining continuous service with territorial recruiting as it did, it consisted of men of a better stamp than the casually recruited regular forces. In those days, the militia was a county force commanded by the lords-lieutenant and officered by men of influence; it was not administered by the War Office.

In other countries, Napoleon's invading armies had only to deal with regular or professional troops. Once these were crushed, nothing remained for the beaten side but to make peace with the conqueror on such terms as could be obtained. Militias existed in name as organizations, for the production of more or less unwilling drafts for the line, but the fundamental militia obligation of defending the fatherland as distinct from defending the state, produced only local and occasional outbursts of guerrilla warfare. In the Crimean War, the 1859 war in Italy, the 1866 war in Germany, and other wars (the Hungarian War of 1848–49 excepted) the forces, other than the regular troops, engaged in line were guerrilleros, insurgents, Garibaldis, &c., and behind the forces in line there were the policing agencies, but no true militia. Only the British militia and the Prussian Landwehr reduced the self-contained army of second line, and of those the former was the most noted. To the test, while the latter, responding feebly to a political call to arms in 1830, was in consequence so entirely reorganized that it formed a mere rear rank to the line troops. This latter system, consecrated by the German successes of 1870, became the universal model for the continent of Europe, and organized and self-contained militias to-day are only to be found in states maintaining line armies of "general service" professionals, or in states which maintain no first line troops whatever. In the first class are the auxiliary forces of the British Empire and the United States, in the second the Swiss, Norwegian, Dutch and Swedish forces.

MILITIA OF THE UNITED KINGDOM

The title of "militia" disappeared from the list of the British forces in 1908, on the conversion of the existing self-contained Militia System, which is in many respects restricted to the rôle of providing drafts for the first line.1 The "self-contained" second line army of the present day is the Territorial Force (see United Kingdom: Army).

The county organization of England, with which throughout the militia was closely associated, began with the advent of the Saxons. The prototype of the militia was the fyrd. In this force as reorganized by Alfred liability of service was general on the part of all able-bodied male-borne citizens between the ages of 16 and 50. Although the title of "The Fyrd" survived until long after the Norman Conquest, the force established by King Alfred was known as the general levy, which was bound to appear armed when ordered to aid in suppressing domestic riots as well as in defending the realm against invasion by foreign foes. Service was restricted to the counties, except in case of invasion, when it was extended to the whole kingdom. For centuries these remained with little alteration as the principles governing the national forces of the Kingdom, and a distinction of effect with a large area of definition is the fundamental principle of the modern Militia System. The Norman Conquest was immediately followed by the introduction of the feudal levy in addition to the general levy, the distinction between these forces being that while obligation to serve in the latter rested upon every male within certain limits of

1 Various dominions and colonies of the British Empire have militias, for which see United Kingdom: Army. For the Swiss Militia System, see Switzerland; for the archetype of modern militias, see Switzerland; and for the organized militia of the United States see United States.
MILITIA

age, service in the feudal levy depended upon tenure of land under the
king as feudal lord. The general levy was not in any case stroke
service for overseas, but the king for a long time employed his
feudal tenants in continental wars until they too, successfully resisted the
taxation. Service for defense, enforcement of laws, and maintenance of
service by deputy, or payment in lieu of personal service, and the
listing out of a quota only, were allowed to very early times.
The feudal levy was discontinued during the Commonwealth and abol-
ished for a time by Cromwell; but by a statute of the reign of
and the assembly and training of the men raised under this national
system were secured from time to time by means of "asses of arms," "as
arms of armory," "commissions of array," and "com-
missions of arms," the last being from the Restoration to the present
of the 16th century. The machinery employed to carry out the law
formed the basis of the existing procedure for the enforcement of
the ballot for the militia, which thus bears a strong resemblance to
the methods employed in the long line of levies. The levies were frequented by "electing" or impressing men to
serve out of the kingdom, but this was checked in the year 1577 by an
Act of Parliament, which strictly regulated the scope and limits of
military service within the kingdom at the charge of the parishes or
counties. The military service and commissions the militia
"Commissions of musters" were a development of preceding
measures for raising men and material for military service, under
which the commissioners raised and mustered persons liable to
service. These bodies first came into existence in the reign of
Queen Mary, and were continued after the Restoration as appointed officers for the militia,
their commissions at the present day being issued under the Militia
Act. There does not appear to have been any clearly defined
regulation as to the procedures, but the Acts of the Commonwealth
were called into active service, but the Acts of the Commonwealth
supplied this defect, and initiated a permanent regimental system.
One of the earliest attempts to reform the forces for the time of
King Charles II was the adoption of the idea of promoting officers
by instructing lords lieutenant to put the militia on a better
footing and to fill up vacancies among the officers. Cromwell
subsequently issued similar orders couched in strong terms, though
under the constitution of the colonies the militia had not been
recognized, the militia being raised by commissions. The great
services rendered by the militia in the "crowning mercy" of
Worcester are a historic exception to the general decedence of second
line troops in the 17th and 18th centuries (see GREAT REBELLION).
At the Restoration an act was passed declaring that the control of
the militia was the prerogative of the king. By the same statute
the militia of each county was placed under the lieutenant, who was
vested with the authority of a commandant of the Crown. The service
was also extended to the various towns and parishes of the
Crowns in the way of commissions and dismissal. The cost of
the annual training—for fourteen days—fell upon the local authority.
Offences against discipline were dealt with by the civil magistrates,
but with the greatest leniency. In the case of the militiamen the
existing laws were sufficient for the purpose, but in the case of the
sailors, and men of the Crown, and gentlemen, the system of fines and
penalties was found to be inadequate. Upon this footing the militia of England remained for nearly
a century with the general approval of the community. It was
recognized as an instrument for defence and for the preservation of
internal order, while it was especially popular from the circumstance that
from its constitution and organization the Crown could
not use it as a means of violating the constitution or abridging the liberty
of the subject. It was controlled and regulated in the county; it was
offered by the landowners and their relatives, its ranks were filled
by persons who were willing to serve for the immediate advantage of
their own benefit. The levy was not a levy of the Crown; its numbers and maintenance were
beyond the royal control; its government was by statute. While
the supreme command was distinctly vested in the Crown, every
practically regulated body in the country, and the service was not
by any object not constitutional or legitimate. It was regarded as,
and was, in fact, the army of the state as distinguished from the
standing army, which was very much the army of the king personally.
The militia was at first recruited by a conscription, confined, however, to persons of the
vagrant class not having a lawful employment, while the former
was mainly composed of those having a fixed abode and status. The
militia was a community with a sense of responsibility and forces a social as well as a constitutional superiority. To this,
however, along with the general breakdown of militia systems under the new "professional" conditions of warfare, explained above, and the tendency of regimental life to encourage a type of personality which
may be termed a "militia man," the militia of the early years was
abolished, the exception of the trained bands of
London, until it was reorganized in 1757. Under the act of 1662
all train bands were discontinued in the counties, but those of Lon-
don, with their auxiliaries, remained until 1794, when they were
reorganized as the City of London Militia. In 1688 an act was
passed raising the militia for one year, and for some time it was an
annually sanctioned force as the regular army is to-day. In 1690,
on the occasion of the threatened French invasion, the militia was
embodied; and again in 1715 and 1745 during the troubles caused
by the Old and Young Pretenders. In a pamphlet of 1712 the Eng-
lish militia was compared to the trained bands of
Scotland at 7,800 horse and 8,300 foot soldiers. From 1715 until 1734, and again from that year until 1757, with
the exception of 1745, no votes were taken in parliament for
the militia.

The foregoing remarks apply only to the English militia and its predecessors. Ireland and Scotland did not furnish any regular
militia until 1715 and 1735 respectively, although in Scotland
militia existed long before; e.g. in Perthshire in 1654; and in
England in military regiments about 1630. The Irish militia
when first raised in 1715 was restricted to Protestants between
the ages of 16 and 50, who were bound to appear or provide substit-
utes. The force was not made subject to military law, but various
enactments and other acts followed until 1739, when a new act
was passed providing for raising a force of militia by ballot among
men between the ages of 18 and 45, to serve for four years. Each
man was expected to provide a gun and to be in sound defile, and enlist-
ment in the army was prohibited. Other amendments followed
from time to time, and notably one in 1797 abolishing religious
restrictions for the supplementary militia, and in 1802 removing the same restrictions in the case of the general militia.

To return to England, the immediate cause of the organic reform
carried out in 1757 was the disclosure of the inefficiency of the militia
during the Rebellion of 1745. The act of 1662 followed the
additional callings the militia were raised and embodied. The Irish
arms in proportion to the value of their property, and the liability
of persons of small property was to be discharged out of a rate levied
in the parish. This was entirely altered in 1757, a liability on the
military service. The act of 1757 provided for the enlistment of a
substitute, and vacates were to be filled from time to time by a
lack process of ballot. The ages of liability were from 18 to 45.
The system thus legalized is practically the existing though sus-
pected ballot system. The force was to be annually trained and exer-
cised for a limited period, and in case of invasion or danger thereof,
or in case of rebellion, the Crown could order it any portion of
it to be embodied; but only on condition of informing parliament
of the same. The act of 1757 was passed out of the favor of the
embodiment or annual training it was subject to the Mutiny
Act, except that no punishment during training was to extend to
"life or limb"; to prevent an unconstitutional use of the militia
force. It was not to be employed by a minister of the sovereign,
not by an executive minister of the sovereign, but by the House of
Commons itself. Upon the initiative of a committee of the house,
the act was passed providing for the pay and clothing of the militia
for the year. The king directly appointed the permanent staff
of officers, who were to have a property qualification.

Under this act 30,000 militiamen were raised by ballot and
embodied from 1759 to 1763. This service was especially "Protestant,
and was for a term of years. The service of the militia was grouped
in 1800 by an act which
arranged remained nearly in the same state until 1870. Pitt's
reform, however, was followed by numerous amendments, new
enactments, and other changes, of which the following is a summary:

1758. Men volunteering to serve recognized as counting towards the quota.
1761. Raising of quota made compulsory on counties under penalty
1765. Mutiny Act applied to militia when out for training as well as when embodied.
1775. (American War.) Act passed empowering embodiment of militia in case of insurrection or rebellion.
1786. Charge on parishes for storage of arms, &c., transferred to counties.
1795. Enlistment into militia encouraged.
1796. The militia were embodied, the number of 29,378 men.
1798. (Irish Rebellion.) English militia volunteered for service in Ireland.
1799. Irish militia volunteered to serve in Great Britain.
1803. 45,942 men raised for militia by ballot, but of these 40,989
were substitutes.
1805. Militia affiliated to line for purposes of recruiting for regulars.
1806. Training Act to raise by ballot 200,000 men to be trained for one whole year, and then to discharge them from training for two years.

1808. Difficulties having arisen under above Act, local militia (with the old general levy) established in addition to general militia then embodied. 27,000 militiamen volunteered to regular army during preceding two months.

1811. Encouraged not to serve out of the kingdom, now made liable to serve in any part of the United Kingdom under certain restrictions, which were subsequently (in 1859) removed.

Method of obtaining men from militia for regulars further detailed.

1812. In this year there were 250 regiments of local militia, with an establishment of 240,388 men and 214,418 actually enrolled.

1813. During the years from 1803 to 1813, nearly 100,000 militiamen joined the regular army.

Act passed to enable militia to serve abroad as militia with their own officers. Three strong battalions joined the British army in France.

1815. Militiamen recruited in great numbers the army which fought at Waterloo. Local militia ceased to be raised.

1816. Local Militia Act suspended.

General militia disbanded.

1820—21—25. Militia called out for training.

1829. Act passed suspending ballot for the general militia.

1831. Militiamen raised by ballot in accordance with Order in Council of December 25, 1830, was the last occasion on which the ballot was put in force.

In the latter stages of the great French war the tendency of the government was to use the general militia rather as a reservoir for producing drafts (in time of war) than as a militia, and the local militia as a national defensive force. During the height of the war (in 1812) the relative position of the various branches of the army was as follows: First line, the standing army; second line, the general or regular militia, which as the war went on were more and more united into one body; third line, the local militia, which was the last source of volunteers, who at that time numbered about 68,000 men. After the peace of 1815 the militia was allowed practically to fall into abeyance, and although the permanent staff was maintained, it had ceased to perform its main functions. In 1838 the Prime Minister, in parliament, to re-establish the militia, but it was not until 1852, after an unsuccessful attempt to resuscitate the local militia, that the general militia of England was reorganized under a system of voluntary enlistment with the ballot in reserve. Scotland and Ireland being included in 1854. The property qualification of officers which had hitherto existed (with exception in favour of ex-officers of the army and navy) was reduced, and after a further reduction in 1863, was totally done away with in 1869. Larger powers respecting the militia were conferred upon the Crown, and during the Crimean War the king was authorized to embody the militia whenever he saw fit. In that war the militia was embodied for the purpose of the transition to the regular army, but in the Mediterranean garrisons, thus enabling the authorities to send most of the available regular troops to the scene of hostilities. It further contributed many officers and some 30,000 men to the line. During the Indian Mutiny it filled scarcely less useful functions when again called out. The territorial force when created served in the Channel Islands and Isle of Man was definitely authorized in 1859, and extended to service in Malta and Gibraltar in 1875.

In 1871 an important constitutional change was made. It was part of the new system inaugurated in that year the control of the militia should be removed from the lord-lieutenant of the county and vested wholly in the Crown. It now virtually ceased to exist as a distinct body, and in 1881 it became a part of the regular forces, and was subject to the time and cost conditions of service. Militia battalions were united with the line battalions to form territorial regiments, the artillery and engineers being also closely associated with the regular services. Various amendments and extensions of the militia system, and the introduction of the discharge system, increased the usefulness of the militia, rendering it more efficient and ready for service, though at the same time making it more and more a means for supplying recruits, both officers and men, to the regular army. The officer of non-commissioned men was made subject at all times to military law. Non-commissioned officers and men were only so subject when embodied or out for training, with extension in the case of men convicted of offences committed during training until the expiration of the punishment. Enlistment was voluntary, compulsory service by ballot remained legal, but suspended. The period of engagement was for six years, re-engagements for periods of four years up to the age of 45 being permitted. Booties were paid to militiamen at various rates upon enlistment, conclusion of training, re-engagement, enlistment for the reserve or special service section, and other special circumstances. Recruit training maximised to 9 months as the rule did not exceed three months. Recruits were either drilled immediately upon enlistment at any time of the year, which is now the most usual system, or else at preliminary drills (first instituted in 1866), immediately preceding the main training. Length of term and annual training varied with the different branches of the service. The special term for infancy was 27 days, but when on manoeuvres this was generally extended to 34 days, 56 days being the legal maximum. A similar drill and training for the non-commissioned officers and mining engineers for 55 days. Trainings took place for the most part in camp or barracks, and large numbers of militia battalions were latterly called on to take part in field manoeuvres. The militia despatched as a rule the same barracks, and for a few months were (with slight distinctions) the same uniform as the regulars.

The militia occupied an important position in the mobilization scheme for national defence. The permanent staff (adjudant, quartermaster, and an establishment of non-commissioned officers and buglers or drummers, all regulars) was engaged during the non-training period of the year in recruiting, care of arms, clothing &c., and in drilling recruits. The general lines of the system, as well as the training, are described under the special reserve, though the constitution of the new force is very different.

The militia ordinarily was liable only for service in the United Kingdom, but by legislation in 1859 may voluntarily serve in any part of the world, including India. During 1859-1900, 22,000 militiamen were thus engaged, and the bulk of them proceeding to the seat of war in South Africa.

The militia reserve consisted of men selected from the ranks of the militia for special enlistment for service in the regular army when called upon in emergencies, in the following proportions: India 5,000 men, the Mediterranean 68,000 men, and the rest of the world as the special reserve. The militia reserve was therefore a complete misnomer, and the force so called was purely an army reserve. The special service section of the militia was formed by royal warrant in 1857, and consisted of about 250,000 individual militiamen. A militia unit was considered as available for special service if not less than 75% of the officers and men present at training made a voluntary offer to engage for special service in any part of the world. The reserve of the militia reserve was the infantry, and in the artillery at least 250 men were accepted as qualified. Individual militiamen engaged to serve either with their militia unit if it were registered for service, or else for special service with the regular forces. Liability for further re-engagement limited to twelve months. Men of the special service section could also be called for service and the number of men to be enlisted was determined in addition to that given for the reserve. The result of this special section was not up to 1900 satisfactory. Very few units could qualify for registration, and the response of individual men was consequently insignificant.

During and after the South African War, while militia recruiting for the regulars showed a constant increase compared with preceding years, the strength of the militia itself decreased year after year. Its militia character had been diminishing ever since the creation of the "military reserve" and the close affiliation of the force to the regular army. For good or evil, then, it had become in the first place a draft-producing agency, and on the reorganization of the forces of the Crown into two lines by Mr. Haldane the old "constitutional force" was formally reorganized as a reserve for the line, enlistment and training conditions remaining somewhat similar to those in vogue in the militia, but the liability for service abroad becoming the first and most important condition in the "special reserve" for military service.

MILK (O. Eng. meāl; cf. Lat. māla, Gr. μαλαξία), the fluid secreted by the mammary glands of the division of the placental mammals Mammalia (see MAMMARY GLAND), and primarily devised for the nourishment of their own young.

The milk of various domesticated animals is more or less used by man for food. The milk of the cow, which may be taken as typical of all others, and is indeed by far the most important and valuable of all (see DAIRY AND DAIRY FARMING), is, when newly drawn, an opaque white fluid, with a yellowish tinge, soft, bland and sweetish to the taste, and possessed of a faint animal odour. This odour, according to Schreiner, is due to the presence of sulphuretted hydrogen, and disappears after a short exposure. The specific gravity of milk ordinarily ranges from 1.020 to 1.033, very seldom reaching 1.035 or falling so low as 1.027. In chemical constitution it consists of an emulsion
of fatty globules (cream) in a watery alkaline solution of casein, and a variety of sugar, peculiar to milk, called lactose. The fat (which when separated we know as butter) and the lactose constitute the carbonaceous portion of the milk regarded as food. The casein, which forms the principal constituent of cheese, and a certain proportion of albumen which is present, form the nitrogenous, while the complex saline substances and water are the mineral constituents. These various substances are present in the proportions which render milk a perfect and typical food suitable to the wants of the young of the various animals for whom it is provided by nature. The milk of animals, so far as is known, contains them, although they are present in somewhat different proportions. It is probable that the milk of ruminants possesses certain physical and physiological distinctions from that of non-ruminant animals, which will account for the virtues attributed to the milk of the ass and mare. The following table exhibits the chemical constitution of the kinds of milk most frequently used by man:—

In addition to these constituents milk contains small proportions of the gases carbonic acid, sulphuretted hydrogen, nitrogen, oxygen, and minute quantities of other principles, the constant presence and essential conditions of which have not been determined. These consist of galactin and laetochrome, substances peculiar to milk, discovered by Winter Blth, with certain animal principles such as leucin, peptone, creatin, tyrosin, &c. The salts in milk consist, according to the average of numerous analyses by Fleischman, of the following constituents:—

- Phosphoric acid: 28-31 Potash: 17-34
- Chlorine: 16-34 Magnesia: 4-07
- Lime: 27-00 Ferric oxide: 0-62
- Soda: 10-00

Milk thus is not to be regarded as a definite chemical compound even as a mixture of bodies in fixed and invariable proportions. Not only does the milk of different races and breeds of cows vary within comparatively wide limits; the milk of the same animal is subject to extensive fluctuation. The principal causes of variation in the individual are, period of lactation, nature and amount of food, state of health, and treatment, such as frequency of milking, &c. The following table indicates the range of normal variations:—

The average quantity of milk yielded by cows is also highly variable, both in individuals and breeds.

**Milk and Disease.**—Although the milk of a perfectly healthy cow may be absolutely sterile, it is difficult to obtain it in that condition. In the report of the joint committee appointed for the purpose by the county boroughs of Bradford, Hull, Leeds, Rotherham, and Sheffield in 1908, the following conclusions were drawn: (1) Cows' milk freshly drawn from the udder by ordinary methods contains bacteria; (2) there is a greater increase in the milk at each stage before it reaches the customer. This is due to (a) the dirty condition of the cows' udders, (b) the imperfect cleansing of the cans and of the hands of the milkers. The committee recommend:—

- (1) The washing of the udder and flanks with soap and water, and similar attention to the hands of the milkers.
- (2) Efficient sterilization of all vessels by steam if possible, or by abundance of boiling water.
- (3) Rejection of the first draw of milk from each teat.
- (4) Sterilization of empty cans immediately before or during milking.
- (5) Removal of the milk of each cow immediately from the shed.
- (6) Ventilation and cleanliness of the cowsheds.

This provides for the reduction as far as possible of contamination during the milking process itself. As any bacteria present in the milk remain in the milk until it is consumed or sterilized, the agent in this respect is mainly the question of the time which elapses before consumption. It is, therefore, further recommended (a) that the milk be rapidly cooled or chilled, as the lower the temperature the less do the bacteria multiply, (b) that it be consumed during the railway transit be avoided by dust-proof locked milk cans.

By treating milk at a temperature of 60° C. for one hour, 70° C. for ten minutes, and 95° C. for one minute, tubercle bacilli, if present, will be rapidly destroyed and all other micro-organisms are less resistant, and are killed more quickly than by boiling at the above temperatures. Only a single pathogenic species can withstand the short boiling to which milk is ordinarily treated in domestic management, and this is the anthrax bacillus containing spores. The danger from this source is remote, as the microbe does not form spores within the animal body. Even in the worst cases, therefore, only vegetable forms, easily destroyed by boiling, can find their way into the milk from the body of the cow.

The lactose bacillus, always present in unboiled milk (to which the souring of milk is due), is easily destroyed by heat; but the bacillus mesentericus, often found in it, forms spores, which are not destroyed by ordinary boiling, and germinate when the milk is long kept moderately warm, to form a brief fermentation whereby a large volume of gas is liberated. The fundamental idea of Soxhlet's method for sterilizing milk is to boil it for forty minutes in small bottles holding just enough for one meal, and closing the same with an impervious stopper, which is only removed at the last moment, at an ordinary room temperature, as the spores of the B. mesentericus do not develop below 15° C.; but if it be introduced into the alimentary canal of a child the spores will rapidly multiply, and in such cases large quantities of gas are given rise to, with the possibility of also poisonous decomposition products of albuminoid matter to render milk sterile in the strict sense of the word it is necessary to raise it to a temperature of about 120° C. for twenty minutes. Under these conditions of sterilization, the milk loses its emulsified condition and separates out as cream which cannot be made to diffuse again even by shaking, and the albuminoids are converted into a form very difficult of digestion. This cream, being that portion of milk, which is usually found in the milk of large animals, is small milk as prepared by grinding the former in a large scale from germs without at the same time seriously prejudicing its flavour and nutritive value. Since, then, the destruction of the hardy germs is so difficult, the greater care should be taken, by washing the udder, hands and milk vessels, to secure extreme cleanliness in the pasteurization of milk. The sterilization of the milk in this way then becomes an easier task, the milk drawn under these conditions being very poor in spore-forming bacteria. It is imperative that cream destined for butter-making should be free from pathogenic organisms, and that the tuberculous present in butter retain their vitality for a long time. As butter is consumed in the raw state, a trustworthy preliminary treatment of the cream is in the highest degree desirable. Schuppan has shown that it is possible to produce good butter from Pasteurised or even sterilized cream, and Weigmann introduced the plan of artificially souring cream by means of pure cultures of B. acidilactici. Since Mechnikoff's introduction (see LONGEVITY) of the use of sour milk for dietetic purposes—the lactic acid bacillus destroying pathogenic bacteria in the intestines—this has given rise to the multiplication of laboratory preparations containing cultures of the bacillus; and in recent years much benefit to health has, in certain cases, been derived from the discovery.

See the following articles: DAIRY FARMING; INFANCY; DIETETICS; Food and Food Preservation; in the last of which the preparation of condensed milk is described.

**MILKWORT,** in botany, the common name for plants of the genus Polygala (natural order Polygalaceae), a large genus widely dispersed in temperate and tropical regions and represented by a few species in Britain. The common species, P. vulgaris, is a small wiry perennial found on heaths and in meadows throughout the British isles. The stems are 2 to 10 in. long and bear narrow rather tough leaves and small, ½ to ½ in. long, white, pink, blue, lilac or purple flowers. The flowers (see fig.) are peculiar in form and arrangement of parts; they have five free sepals, the two inner of which are large petaloid and wing-like, forming the most conspicuous part of the flower; the petals are united below with the sheath of the eight stamens forming a tube split at the base behind; their form recalls that of the pea family. The name Polygala is from the Greek πολυς, much,
and y\textit{ale}, milk, the plant being supposed to increase the yield of milk in cows. Some species with showy flowers are known in cultivation as greenhouse, or hardy annual or perennial, herbs or shrubs. The root of \textit{P. Senega}, snake-root, a North American species is officinal. Sea milkwort is the common name for \textit{Glaux maritima}, a small succulent herb found on seashores and in estuaries in the British Isles; it belongs to the primrose order (Primulaceae).

\textbf{MILL, JAMES} (1773–1836), historian and philosopher, was born on the 6th of April 1773, at Northwater Bridge, in the parish of Logie-Pert, Forfarshire, the son of James Mill, a shoemaker. His mother, Isabel Fenton, of a good family which had suffered from connexion with the Stuart rising of 1745, resolved that he should receive a first-rate education, and sent him first to the parish school and then to the Montrose Academy, where he remained till the unusual age of seventeen and a half. He then entered the University of Edinburgh, where he distinguished himself as a Greek scholar. In October 1798 he was licensed as a preacher, but met with little success till 1802; in addition to holding various tutorships, he occupied himself with historical and philosophical studies. Finding little prospect of a career in Scotland, in 1802 he went to London in company with Sir John Stuart, then member of parliament for Kin- cardineshire, and devoted himself to literary work. From 1803 to 1806 he was editor of an ambitious periodical called the \textit{Literary Journal}, which professed to give a summary view of all the leading departments of human knowledge. During this time he also edited the \textit{St James's Chronicle}, belonging to the same proprietor. In 1804 he wrote a pamphlet on the corn trade, arguing against a bounty on the exportation of grain. In 1803 he published a translation (with notes and quotations) of C. F. Villers's work on the Reformation, an unsparring exposure of the alleged vices of the papal system. In 1805 he married Harriet Burrow, whose mother, a widow, kept an establishment for lunatics in Hoxton. He then took a house in Cavendish Square, where his eldest son, John Stuart Mill (eq.), was born in 1806. About the end of this year he began his \textit{History of India}, which he took twelve years to complete, instead of three or four, as he had expected.

In 1808 he became acquainted with Jeremy Bentham, and was for many years his chief companion and ally. He adopted Bentham's principles in their entirety, and determined to devote all his energies to bringing them before the world. Between 1806 and 1818 he wrote for the \textit{Anti-Jacobin Review}, the \textit{British Review} and the \textit{Electric Review}; but there is no means of tracing his contributions. In 1808 he began to write for the \textit{Edinburgh Review}, to which he contributed steadily till 1813, his first known article being \textit{"Money and Exchange."} He also wrote on Spanish America, China, General Miranda, the East India Company, and the Liberty of the Press. In the \textit{Annual Review} for 1808 two articles of his are traced—a \textit{"Review of Fox's History of Austria"} and an article \textit{"On Bentham's Law Reform,"} probably his first published notice of Bentham. In 1811 he co-operated with William Allen (1770–1843), quaker and chemist, in a periodical called the \textit{Philanthropist}. He contributed largely to every number—his principal topics being Education, Freedom of the Press, and Prison Discipline (under which he expounded Bentham's \textit{Panopticon}). He made powerful onslaughts on the Church in connexion with the Bell and Lancaster controversy, and took a prominent part in the discussions which led to the foundation of London University in 1825. In 1814 he wrote a number of articles, containing an exposition of utilitarianism, for the supplement to the fifth edition of the \textit{Encyclopaedia Britannica}, the most important being those on \textit{"Jurisprudence,"} \textit{"Prisons"} and \textit{"Government."}

In 1818 the \textit{History of India} was published, and obtained a great and immediate success. It brought about a change in the author's position. The year following he was appointed an official in the India House, in the important department of the examiner of Indian correspondence. He gradually rose in rank till he was appointed, in 1830, head of the office, with a salary of £1900, raised in 1836 to £2000. His great work, the \textit{Elements of Political Economy}, appeared in 1821 (3rd revised ed. 1826). From 1824 to 1826 Mill contributed to the \textit{Westminster Review}, started as the organ of his party, a number of articles in which he attacked the \textit{Edinburgh and Quarterly Reviews} and ecclesiastical establishments. In 1829 appeared the \textit{Analysis of the Human Mind}. From 1831 to 1833 Mill was largely occupied in the defence of the East India Company, during the controversy attending the renewal of its charter, he being in virtue of his office the spokesman of the court of directors. For the \textit{London Review}, founded by Sir William Molesworth in 1834, he wrote a notable article entitled \textit{"The Church and its Reform,"} which was much too sceptical for the time, and injured the \textit{Review}. His last published book was the \textit{Fragment on Mackintosh} (1835). He died on the 23rd of June 1836.

Mill had a thorough acquaintance with Greek and Latin literature, general history, political, mental and moral philosophy. His intellect was logical in the highest degree; he was clear and precise, an enemy of all metaphysical reasoning, and quick to refute prevailing fallacies. All his works are marked by the original constructive thought, except in a few subjects, in which he confessedly expounded Bentham's views. At a time when social subjects were as a rule treated empirically, he brought first principles to bear at every point. His greatest literary monument is the \textit{History of India}. The materials for narrating the acquisition by England of its Indian Empire were put into shape for the first time; a vast body of political theory was brought to bear on the delineation of the Hindu civilization; and the conduct of the actors in the successive stages of the conquest and administration of India was subjected to a severe criticism. The work itself, and the author's official connexion with India for the last seventeen years of his life, effected a complete change in the whole system of governing that country.

Mill played a great part also in English politics, and was, more than any other man, the founder of what was called \textit{"philosophic radicalism."} His writings on government and his personal influence among the Liberal politicians of his time determined the change of view from the French Revolution theories of the rights of man and the absolute equality of men to the claiming of securities for good government through a wide extension of the franchise. Under this banner it was that the Reform Bill was fought and won. His \textit{Elements of Political Economy}, which was intended only as a textbook of the subject, shows all the author's precision and lucidity. As Dr J. K. Ingram said, it has the \textit{"character of a work of art."} It followed up the views of Ricardo, with whom Mill was always on terms of intimacy. Its interest is mainly historical, as an accurate summary of views which are now largely discarded. Among the more important of its theses are: (1) that the chief problem of practical reformers is to limit the increase of population, on the assumption that capital does not naturally increase at the same rate as population (ii. § 2, art. 3); (2) that the value of a thing depends entirely on the quantity of labour put into it; and (3) that what is now known as the \textit{"unearned increment"} of land is a proper object for taxation. The work as a whole is a striking example of the weakness of treating
MILL, JOHN—MILL, JOHN STUART

Ecclesiastical History, M'Crie’s Knox, and two histories of the Quakers. A contemporary record of Mill’s studies from eight to fourteen is published in Bain’s sketch of his life. It shows that the Autobiography rather understates the amount of work done. At the age of eight he began Latin, Euclid, and algebra, and was appointed schoolmaster to the younger children of the family. His main reading was still history, but he went through all the Latin and Greek authors commonly read in the schools and universities, besides several that are not commonly read by undergraduates. He was not taught to compose either in Latin or in Greek, and he was never an exact scholar; it was for the subject matter that he was required to read, and by the age of ten he could read Plato and Demosthenes with ease. His father’s History of India was published in 1818; immediately thereafter, about the age of twelve, John began a thorough study of the scholastic logic, at the same time reading Aristotle’s logical treatises in the original. In the following year he was introduced to political economy and studied Adam Smith and Ricardo with his father.

Not unnaturally the training which the younger Mill received has aroused amazement and criticism; and it is reasonable to doubt whether the material knowledge which he retained in the result was what he had acquired. It is important, however, to note that the truly important part of the training was the close association which it involved with the strenuous character and vigorous intellect of his father. From his earliest days he spent much time in his father’s study and habitually accompanied him on his walks in North London. Much therefore of what he acquired was assimilated without difficulty, and the accuracy of his impressions was tested by his subsequently drafting a résumé of their conversations. He thus learned early to grapple with difficulties and to accustom himself to the necessity of precision in argument and expression. It was an inevitable result of such an education that Mill acquired many of his father’s speculative opinions, and his father’s way of defending them. But he did not receive the impression passively and mechanically. “One of the grand objects of education,” according to the elder Mill, “should be to create a constant and anxious concern about evidence.” The duty of collecting and weighing evidence for himself was at every turn impressed upon the boy; he was taught to accept no opinion on authority. He was deliberately educated as an apostle, but it is true that as an apostle of reasoned truth in human affairs, not as an apostle of any system of dogmatic tenets. It was to prevent any falling off from this high moral standard that it should become part of his being that his father kept the boy so closely with himself. Mill expressly says that his childhood was not unhappy. It seems unhappy only when we compare it with the normal life of a boy and decline to imagine its peculiar enjoyments and aspirations. Mill complains that his father often required more than he could be expected of him, but his tasks were not so severe as to prevent him from growing up a healthy and high-spirited boy, though he was not constitutionally robust, and his pursuits were so different from those of other boys of the same age.

From May 1820 till July 1821 Mill was in France in the family of Sir Samuel Bentham, brother of Jeremy Bentham. Away from his father he maintained his laborious habits. Copyist extracts from a diary kept by him have been given by him. It shows methodically he read and wrote, studied chemistry and botany, tackled advanced mathematical problems, made notices on the scenery and the people and customs of the country. He also gained a thorough acquaintance with the French language. On his return in 1821 he added to his work the study of psychology, and that of Roman law, which he read with John Austin, his father having half decided on the bar as the best profession open to him. In 1822, however, when he had just completed his seventeenth year, this intention was abandoned, and he entered as a clerk in the examiner’s office of the India House, “with the understanding that he should be employed from the beginning in preparing drafts of despatches, and be thus trained up as a successor to those who then filled the highest departments of the office.”
MILL, JOHN STUART

Mill's work at the India House, which was henceforth his livelihood, did not come before the public; hence some have scoured his political writings as the work of an abstract philosopher, entirely unacquainted with affairs. From the first he was more than a clerk, and after a short apprenticeship he was promoted, in 1828, to the responsible position of assistant-examiner with a salary of £600 a year. The duty of the so-called examiners was to examine the letters of the agents of the Company in India, and to draft instructions in reply. The character of the Company's government was almost entirely dependent upon their abilities as statesmen. For twenty years, from 1836 (when his father died) to 1856, Mill had charge of the Company's relations with the native states, and in 1856 he became chief of the office with a salary of £2000. In the hundreds of despatches that he wrote in this capacity, much, not only to the "Utilitarian Question", but to the whole of political and moral philosophy, was written, and many statesmen of his generation had a wider experience of the responsible application of the principles of government. About this work he said little in the Autobiography, probably because his main concern there was to expound the influences that effected his moral and mental development.

About the time of his entering the India House Mill read Dumont's exposition of Bentham's doctrines in the Traité de Législation, which made a lasting impression upon him. When he laid down the last volume, he says, he had become a different being. It gave unity to the detached and fragmentary parts of his knowledge and beliefs. The impression was confirmed by the study of the English psychologists, as well as Condillac and Helvetius, and in 1822–1823 he established among a few friends the "Utilitarian Society", taking established routine, but free from the hardening of the mind's generation, had a wider experience of the responsible application of the principles of government. About this work he said little in the Autobiography, probably because his main concern there was to expound the influences that effected his moral and mental development.

The first sketch of Mill's political philosophy appeared in a series of contributions to the Examiner in the autumn of 1830 entitled "Prospects in France." He was in Paris soon after the July Revolution, and made the acquaintance of the leading spirits among the younger men; in his discussion of their proposals we find the germs of many thoughts afterwards more fully developed in his Representative Government. It is from this time that Mill's letters supply a connected account of his life. The letters with Elizabeth Letters of John Stuart Mill, 1909.

The letters in the Examiner may be taken as marking the close of his period of meditative search, and his return to hopeful aspiring activity. It was characteristic of his nature that he should be stirred to such delight by the Revolution in France, and should labour so earnestly to make his countrymen understand with what gravity and sobriety it had been effected. Their own Reform Bill came soon after and it is again characteristic of Mill—at once of his enthusiasm and of his steady determination to do work that nobody else seemed able or willing to do—that we find him in the heat of the struggle in 1831 writing to the Examiner a series of letters on "The Institute of the Age" which drew from Carlyle the singular exclamation "Here is a new mystic!" How little this criticism was justified may be seen from his work "a purely factitious metaphysical system of his aspirations after political stability as determined by the doctrine of the wisest (Examiner letters). "Why is it," he asked, "that the multitude accept implicitly the decisions of the wisest, of the specially skilled, in physical science?" Because in physical science there is all but complete agreement in opinion. "And why this agreement?" Because all accept the same methods of investigation, the same tests of truth. Is it possible then to obtain unanimity as to the methods of arriving at conclusions in social and political matters, so as to secure similar agreement of opinion among the specially skilled, and similar general respect for their authority? The same thought appears in a review of Herschel's Natural Philosophy, written about the same time. Mill remarks that the uncertainty hanging over the very elements of moral and social philosophy proves that the means of arriving at the truth in those sciences are not yet
properly understood. "And whither," he adds, "can mankind so advantageously turn, in order to learn the proper means, and to form their minds to the proper habits, as to that branch of knowledge in which by universal acknowledgment the greatest number of truths have been ascertained, and the greatest possible degree of certainty arrived at?"

By 1831 the period of depression had passed; Mill's enthusiasm for humanity had been thoroughly reawakened, and had taken the definite shape of an aspiration to supply an unimpeachable method of search for conclusions in moral and social science. No mystic ever worked with warmer zeal than Mill. But his zeal encountered a check which baffled him for several years, and which left its mark in various inconsistencies and incoherences in his completed system. He had been bred by his father in a great veneration for the syllogistic logic as an antidote against confused thinking. He attributed to his early discipline in this logic an impatience of vague language which in all likelihood was really fostered in him by his study of the Platonic dialogues and of Bentham, for he always had in himself more of Plato's fertile ingenuity in canvassing the meaning of vague terms with the right questions in the use of them.

Be this as it may, enthusiastic as he was for a new logic that might give certainty to moral and social conclusions, Mill was no less resolute that the new logic should stand in no antagonism to the old. In his Westminster Review of Whately's Logic in 1828 (invaluable to all students of the genesis of Mill's logic) he appears, curiously enough, as an ardent and brilliant champion of the syllogistic logic against highfliers such as the Scottish philosophers who talk of "superseding" it by "a supposed system of inductive logic." His inductive logic must "supplement and not supersed." But for several years he searched in vain for the means of concatenation.

Meanwhile, while recurring again and again, as was his custom, to this cardinal difficulty, Mill worked indefatigably in other directions where he saw his way clear. The working of the new order in France, and the personalities of the leading men, had a profound interest for him; he wrote on the subject in the Examiner. He had ceased to write for the Westminster in 1828, but during the years 1832 and 1833 he contributed many essays to Tait's Magazine, the Jurist, and the Monthly Repository. In 1835 Sir William Molesworth founded the London Review with Mill as editor; it was amalgamated with the Westminster (as the London and Westminster Review) in 1836, and Mill continued editor (latterly proprietor also) till 1840. Much of what he wrote then was successively incorporated in his systematic works: some of his essays were reprinted in his first two volumes of Dissertations and Discussions (1859). The essays on Bentham and Coleridge constituted the first manifesto of the new spirit which Mill sought to breathe into English Radicals. But the reprinted papers give no just idea of the immense range of Mill's energy at this time. His position in the India Office, where alone he did work enough for most men, cut him off from entering parliament; but he laboured hard though ineffectually to influence the legislature from without by combating the disposition to rest and be thankful. In his Autobiography he admits that the attempt to form a Radical party in parliament at that time was "imbecile." It was in 1837, on reading Whewell's Inductive Sciences and re-reading Herschel, that Mill at last saw his way clear both to formulating the methods of scientific investigation and joining on the new logic as a supplement to the old. The Logic was published in 1843. In 1844 appeared his Essays on Some Unsettled Questions in Political Economy. These essays were worked out and written many years before, and show Mill in his first stage as a political economist. Four out of the five essays are elaborate and powerful solutions of perplexing technical problems—the distribution of the gains of international commerce, the influence of consumption on production, the definition of productive and unproductive labour, the precise relations between profits and wages. Though Mill appears here purely as the disciple of Ricardo, striving after more precise statement, and reaching forward to further consequences, we can well understand in reading these essays how about the time when he first sketched them he began to be conscious of power as an original and independent thinker.

The originality and independence became more conspicuous when he reached his second stage as a political economist, struggling forward towards the standpoint from which his systematic work was written. It would seem that in his fits of despondency one of the thoughts that marred his dreams of human improvement was the apparently inexorable character of economic laws, condemning thousands of labourers to a cramped and miserable existence, and thousands more to semi-starvation. From this oppressive feeling he found relief in the thought set forth in the opening of the second book of his Political Economy—that, while the conditions of production have the necessity of physical laws, the distribution of what is produced among the various classes of producers is a matter of human arrangement, dependent upon alterable customs and institutions. There can be little doubt that this thought, whether or not in the clear shape that it afterwards assumed, was the germ of all that is most distinctive in his system of political economy. This system, which for many years subsequently was regarded as authoritative, has been subjected to vigorous criticism by later economists, and it is perhaps not too much to say that it now possesses merely an historical interest. Its chief importance is perhaps the statement that it laid on the vital connexion which must subsist between true economic theory and the wider facts of social and national development.

While his great systematic works were in progress, Mill wrote very little on events or books of the day. He turned aside for a few months from his Political Economy during the winter of the Irish famine (1846-1847) to advocate the creation of peasant-proprietorships as a remedy for distress and disorder in Ireland. He found time also to write elaborate articles on French history and Greek history in the Edinburgh Review apropos of Michelet, Guizot and Grote, besides some less elaborate essays.

The Political Economy was published in 1848. Mill could now feel that his main work was accomplished; he remained, however, on the alert for opportunities of useful influence, and pressed on with hardly diminished enthusiasm in his search for useful truth. Among other things, he made a more thorough study of socialists writers, with the result that, though he was not converted to any of their schemes, he began immediately practicable, he began to look upon some more practical distribution of the produce of labour as a practicability of the remote future, and to dwell upon the prospect of such changes in human character as might render a stable society possible without the institution of private property. This he has called his third stage as a political economist, and he says that he was helped towards it by the lady, Mrs Taylor, who became his wife in 1851. It is generally supposed that he writes with a lover's extravagance about this lady's powers when he compares her with Shelley and Carlyle. But a little reflection will show that he wrote with his usual accuracy and sobriety when he described her influence on him. He expressly says that she owed none of his technical doctrine to her, that she influenced only his ideals of life for the individual and for society; the only work perhaps which was directly inspired by her is the essay on the enfranchisement of women (Dissertations, vol. ii.). It is obvious from what he says that his marriage became very different after he threw off his father's authority. This new inner life was strengthened and enlarged by Mrs Taylor.

While during the seven years of his married life Mill published less than in any other period of his career, but four of his most
closely reasoned and characteristic works, the *Liberty*, the *Utilitarianism*, the *Thoughts on Parliamentary Reform*, and the *Subjection of Women*, besides his posthumously published essays on *Nature and on the Utility of Religion*, were, for the most part, written in collaboration with his wife. In 1856 he became head of the examiner's office in the India House, and for two years, till the dissolution of the Company in 1858, his official work, never a light task, kept him fully occupied. It fell to him as head of the office to write the defence of the Company's government of India when the transfer of its powers was proposed. Mill was earnestly opposed to the transfer, and the documents in which he substantiated the proud boast for the Company that "few governments, even under far more favourable circumstances, have attempted so much for the good of their subjects or carried so many of their attempts to a beneficial issue," and exposed the defects of the proposed new government, are models of trenchant and dignified pleading.

On the dissolution of the Company Mill was offered a seat in the new council, but declined, and retired with a pension of £1500. His retirement from official work was followed almost immediately by his wife's death at Avignon, whither they had come in the course of a tour. So great was the shock of the rest of his life he built a villa at St Véran, near Avignon, returning to his Blackheath residence only for a short period in each year. He sought relief in active literary occupation, in politics, sociology and psychology. He published, with a touching dedication to his wife, the treatise on *Liberty*, which they had wrought out together. He then turned to politics, and published, in view of the impending Reform Bill, a pamphlet on parliamentary reform. The chief feature in this was an idea concerning which he and Mrs Mill often deliberated—the necessity of providing checks against undemocratic democracy. His suggestion of a plurality of votes, proportioned to the elector's degree of education, was avowedly put forward only as an ideal; he admitted that no authentic test of education could for the present be found. An anonymous Conservative caught at the scheme in another pamphlet, proposing income as a tax. Soon after Mill supported in Fraser's, still with the same object, Hare's scheme for the representation of minorities. In the autumn of the same year he turned to psychology, reviewing Bain's work in the *Edinburgh Review*. In his *Representative Government* (1860) he systematized opinions already put forward in many casual articles and essays. His *Utilitarianism* (published in Fraser's in 1861) was a closely-reasoned systematic attempt to answer objections to his ethical theory and remove misconceptions of it. He was especially anxious to make it clear that he included in "utility" the pleasures of the imagination and the gratification of the higher emotions, and to show how powerfully the good of mankind as a motive appealed to the imagination. His next treatise, *The Subjection of Women*, was not published till 1869.¹ His *Examination of Hamilton's Philosophy*, published in 1865, had engaged a large share of his time for three years before.

While mainly occupied in those years with philosophical studies, Mill did not remit his interest in current politics. He supported the North in the American crisis of 1862, using all his strength to explain what has since been universally recognized as the issue really at stake in the struggle, the abolition of slavery. It was characteristic of the closeness with which he watched current events, and of his zeal in the cause of "liberty," that when the *Reader*, an organ of science and unparliament opinion, fell into difficulties in 1863 Mill joined with some distinguished men of science and letters in an effort to keep it afloat. He supplied part of the money for carrying it on, contributed several articles, and assisted the editor, Fraser Rae, with his advice. The effort was vain, though such men as Herbert Spencer, Huxley, Tyndall, Cairnes, Mark Pattison, F. Harrison, Sir Frederick Pollock and Lockyer were among the contributors.

In 1865 he agreed to stand as parliamentary candidate for Westminster, on conditions strictly in accordance with his principles. He would not canvass, nor pay agents to canvass for him, nor would he engage to attend to the local business of the constituency. He was with difficulty persuaded even to address a meeting of the electors. The story of this remarkable election has been told by James Beal, one of the most active supporters of Mill's candidature. In parliament he adhered to his life-long principle of doing only work that needed to be done, and that nobody else seemed equally able or willing to do. It may have been a consciousness of this fact which prompted a remark, made by the Speaker, that Mill's presence in parliament elevated the tone of debate. The impression made by him in parliament is in some danger of being forgotten, because he was not instrumental in carrying any great measure that might serve as an abiding memorial. But, although his first speech on the bill for the prevention of cattle diseases excited the opposition of country members, and a subsequent speech against the suspension of the Habeas Corpus Act in Ireland was very unfavourably received, Mill thoroughly succeeded in gaining the ear of the House. The second speech on a post-war scheme of government for Ireland was listened to with impatience was, curiously enough, his speech in favour of counteracting democracy by providing for the representation of minorities. His attack on the conduct of Governor Eyre in Jamaica (q.v.) was listened to, but with repugnance by the majority, although his action in this matter in and out of parliament was far from being ineffectual. He took an active part in the debates on Disraeli's Reform Bill (moving an amendment to omit the word "man" and insert "person"), and helped to extort from the government several useful modifications of the Bill for the Prevention of Corrupt Practices. The reform of land tenure in Ireland, the representation of women, the reduction of the national debt, the reform of London government, the abrogation of the Declaration of Paris, were among the topics on which he spoke with marked effect. He took occasion more than once to enforce what he had often advocated in writing, England's duty to intervene in foreign politics in support of the cause of oppressed minorities, and to do so hesitating, pausing occasionally as if to recover the thread of his argument. He showed great readiness in extemporaneous debate. Viewed as a candidate for ministerial office, he might be regarded as a failure in parliament, but there can be no doubt that his career there greatly extended his influence.

Mill's subscription to the election expenses of Bradford, and his attitude towards Governor Eyre, are generally regarded as the main causes of his defeat in the general election of 1868. But, as he suggests himself, his studied advocacy of unfamiliar projects of reform had made him unpopular with "moderate Liberals." He retired with a sense of relief to his cottage and his literary life at Avignon. His parliamentary duties and the quantity of correspondence brought upon him by increased publicity had absorbed nearly the whole of his time. The scanty leisure of his first recess had been devoted to writing his St Andrews rectorial address on higher education and to answering attacks on his criticism of Hamilton; of the second, to annotating in continuation with Bain and Findlater, his father's *Analysis of the Mind*. Now he looked forward to his literary life, and his letters show how much he enjoyed the change. His little cottage was filled with books and newspapers; the beautiful country round it furnished him with a variety of walks; he read, wrote, discussed, walked, botanized. He was extremely fond of music, and was himself a fair pianist. His step-daughter, Miss Taylor (d. January 1907), was his constant companion after his wife's death. "Helen," he wrote to W. T. Thornton, an old colleague in the India House, "has carried out her long-cherished scheme (about which she tells me she consulted you) of a 'vibratory' for me, and has made a pleasant covered walk, some 30 ft. long, where I can vibrate in cold or rainy weather. The terrace, you must know, as it goes round two sides of the house, has got itself

¹ He was one of the founders, with Mrs P. A. Taylor, Miss Emily Davies and others, of the first women's suffrage society, which developed into the National Union of Women's Suffrage Societies, and his writings are still the most important theoretical statement of the case for women's suffrage. He presented to Parliament the first petition on the subject (see further Blackburn, *Women's Suffrage Record*).
MILL, JOHN STUART

458

Dubbed the 'semi-circumgyratory,' in addition to this, Helen has built me a herbarium, a little room fitted up with closets for my plants, shelves for my botanical books, and a great table. I date this from the time when I took to herbarium, my vibratory, and my semi-circumgyratory. I am in clover; and you may imagine with what scorn I think of the House of Commons, which, comfortable club as it is said to be, could offer me none of these comforts, or, more perfectly speaking, these necessary of life. Mill was an enthusiastic botanist all his life long, and a frequent contributor of notes and short papers to the Phytologist. One of the things that he looked forward to during his last journey to Avignon was seeing the spring flowers and completing a flora of the locality. His delight in scenery frequently appears in letters written to his friends during his summer and autumn tours.

Yet he did not relax his laborious habits nor his ardent outlook on human affairs. The essays in the fourth volume of his Dissertations—on endowments, on land, on labour, on metaphysical and psychological questions—were written for the Fortnightly Review at intervals after his short parliamentary career. One of his first tasks was to send his treatise on the Socialist Embankment, the last part of the third quarter of the 19th century, even later. In philosophy his chief work was to systematize and expound the utilitarianism of his father and Bentham (see Utilitarianism). He may, if, in fact, be regarded as the final exponent of the empirical school of philosophy which owed its impetus to John Locke, and is generally spoken of as being typically English. Its fundamental characteristic is the emphasis laid upon human reason, i.e., upon the duty incumbent upon all thinkers to investigate for themselves rather than to accept the authority of others. Knowledge must be based upon experience. In asserting and amplifying the empirical conclusions of his predecessors, especially in the sphere of ethics, Mill's chief function was the introduction of the humanistic element, which to some extent was derived from his own upbringing and the period of stress through which he passed in early manhood, but also to the sympathetic and emotional qualities which manifested themselves in his early manhood. We have seen that Mill was bred to the law; he was never a lawyer, he was because he found in attempting to advance his humanitarian schemes in politics an absence of that fundamental agreement which he recognized as the basis of scientific advance. Both his logical and his metaphysical conceptions were thus undertaken as the pre-requisites of a practical theory of human development. Though he believed that the lower classes were not yet ripe for socialism, with the principles of which he (unlike James Mill and Bentham) was in general agreement, he still regarded the presence of the working classes in those institutions as the very first step in the development of the working classes. This fact, no doubt, should be taken into account in any detailed criticism of the philosophic work; it was taken up not as an end but as an auxiliary to a social and ethical system. Reference to the articles on Logic, Metaphysics, &c., will show that subsequent criticism, however much it has owed by way of stimulus to Mill's strenuous rationalism, has been able to point to much that is inconsistent, inadequate and even superficial in his writings. Two main intellectual movements from widely different standpoints have combined to diminish his influence. On the one hand there has arisen a school of thinkers of the type of Thomas Hill Green, who have brought to bear on his metaphysical views the demand for a more rigorous and logical discipline. On the other hand, the evolutionists, who have substituted for the utilitarian ideal of the 'greatest happiness' those of 'race-preservation' and the 'survival of the fittest' (see Ethics, ad. fn.; Spencer). In the sphere of political philosophy, likewise, have arisen the doctrines of the Association of Ideas (g.v.) and the phrase: 'Mental Chemistry,' by which he sought to meet the problems which Associationism left unsolved—modern criticism and the experimental methods of the psycho-physiological school have set up wholly new criteria, both in terminology and in methods of investigation (see Psychology).

A similar fate has befallen Mill's economic theories. The title of his work, Principles of Political Economy, with some of their Applications to Social Philosophy, 1848, was necessarily a misnomer, for Mill, in his more frequent use of the term 'political economy,' referred to the study of those institutions which are to a greater or less extent affected by the course of business. He pointed out the less narrow and formal conceptions of the field of the science than had been common amongst his predecessors. He aimed in fact at producing a work which might replace in ordinary use the Wealth of Nations, if it did not attain a wider circulation. His chief work, which this opinion was 'in many parts obsolete and in all imperfect.' Adam Smith had invariably associated the general principles of the subject with their applications, and in treating those applications had perpetually appealed to other and often far larger considerations than pure political economy affords. Mill's approach was, therefore, a method of the type set up by modern economics, some of whose results arrived at in the special science by Smith's successors, to exhibit purely economic phenomena in relation to the most advanced conceptions of his own time in the general philosophy of society, as has been done in dominant anthropology. This design he certainly failed to realize. His book is very far indeed from being a 'modern Adam Smith.' It is an admirably lucid, and even elegant, exposition of the Ricardian economics, the economic ethics, the doctrine of population, and the theory of rent, and notwithstanding the introduction of many minor novelties, it is in its scientific substance little or nothing more.

With respect to economic method he shifted his position, yet to the right. He always contended for the autonomy of the sciences, he asserted that the method a priori is the only mode of investigation in the social sciences, and that the method a posteriori is altogether inapplicable in those sciences as a means of arriving at any certain results. He especially held that, by arriving at a method he termed 'Logic' he had learned from Comte that the a posteriori method—"in the form which he chose to call "inverse induction"—was the only mode of arriving at truth in general sociology; and his avowed purpose was to get at these arms at any cost. Thus, being unwilling to relinquish the a priori method of his youth, he tries to establish a distinction of two sorts of economic inquiry, one of which, not the other, can be handled by that method. Sometimes he speaks of political economy in a department "drawn out of the general body of the science of society;" whilst on the other hand the title of his systematic work implies a doubt whether political economy is a part of "social philosophy" at all, and not rather a study preparatory and explanatory of certain parts of his logic, as well as a dogmatic side, he halts between two opinions. Notwithstanding his misgivings and even disdainers, he yet remained as to method a member of the old school, and never passed into the new "historical" school.

Bibliography.—Works: System of Logic (2 vols., 1843; 9th ed., 1875; "People's" ed., 1884); Essays on some Unsettled Questions of Political Economy (1844, ed. 1874); Principles of Political Economy (2 vols., 1848; many ed., especially ed. by W. J. Ashley, 1900); On Liberty (1859; ed. Cousley, 1892; W. B. Columbia, 1903); Three Essays on Religion (1858); Essay on Bentham (1861); Thoughts on Parliamentary Reform (1859); Dissertations and Discussions (i., ii., 1859; iii., 1857; iv., 1876); Considerations on Representative Government (1861); Political Economy (3rd ed. 1863); Utilitarianism: A Sin and a Service (1865); Utilitarianism: A Sin and a Service (1865); An Address to the Members of the Royal Statistical Society (1866); Essays and Lectures (1869); Essays and Lectures (1869); Tho Thoughts on the English Poor Law (1868); Gifts to the Poor (1869); The English Passages and Positions (1865, 1908); Inaugural Address at the University of St Andrews (1867); England and Ireland (1868); Subscriptions of the Women (1869, ed. with introd. by Stanton Colton, 1869); Chapters and Speeches on Irish Rent (1870); Three Essays on Religion (1874). Many of these have been translated into German, and there is a German edition by Th. (12 vols., 1873-1880). A convenient edition in the New Universal Library (5 vols., 1899). Biographical and Critical.—Many of Mill's letters are published in Mrs Grote's life of her husband, in Duncan's Life of Herbert Spencer, in the Memoirs of Caroline Fox, and in King's letters. There are also editions of the correspondence with Gustave Eulacht and with John Stuart Mill, and a correspondence with the Rev. H. H. May, all of which illuminating collection is that of Hugh Elliott, Letters of John Stuart Mill (2 vols., 1910), which contains letters to John Sterling, Carlyle, E. Lytton Bulwer (Lord Lytton), John Austin, Alex. Bain, and many leading French and German writers and politicians. These letters are essential to an understanding of Mill's life and thought. Besides the Autobiography and many references in the writings of Mill's friends (e.g. Alex. Bain's Autobiography, 1904), see further

Graham, English Political Philosophy from Hobbes to Maine (1899). There are also a number of valuable French and German criticisms, e.g. Taine, Positivism et science, étude sur Stuart Mill (Paris, 1864); F. A. Lange, Mills Ansichten über die Geschichte der Philosophie (1889). Mill's works have been translated into many languages; see also several histories of modern philosophy.

See further Logic (Historical Sketch); Psychology: Association or Habit (W. M. C.); Unconscious Mental Activities (W. M. C.).

MILL (O. Eng. mylhen, later mylwyn, or milh, adapted from the late Lat. molina, cf. Fr. moulin, from Lat. molere, a mill, to grind; from the same root, molt, is derived "meal," the word appears in other Teutonic languages, cf. Du. molien, Ger. mühle), the term given to the apparatus or machinery used in the grinding of corn into flour, and hence applied to similar mechanical devices for grinding, crushing to powder, or pulsing other substances, e.g. coffee-mill, powder-mill. "Mill" was first used of the building containing the apparatus, frequently with a word attached descriptive of the motive power, e.g. wind-mill, water-mill, &c. It was not the early word used of the actual grinding mechanism. The old hand-mill was known as a "quern," a word which appears in this sense in many Indo-European languages; the ultimate root is gær, to grind. "Quern" (see Flora) is only remotely connected with "churn" (q.v.). The word is also applied to many mechanical devices by which raw material is transformed into a condition ready for use or into a stage preparatory to other processes, e.g. saw-mill, rolling-mill, &c., or still more widely to buildings containing machinery used in manufacturing processes, e.g. cotton-mill. In mining it is applied to various machines used in breaking and crushing the ore (see Ore-Dressing).

In the engineering industries milling machines constitute a very important class of machine tools, the characteristic of which is that rotary cutters are employed for shaping the metal (see Tools). In coins the "milling" is the serrated edge, called "crenell" by John Evelyn (Discourse on Medals, 1607, p. 225), which is formed on them to prevent clipping and filing. Coins made by the old process of hammering were apt to have irregular edges which invited mutilation; but the introduction of the screw press, which came to be known as a mill (cf. W. Lowndes, Amendm. Silver Coinage, 1605, p. 93), permitted the production of a regular edge with serrations, which in consequence were termed milling. This machine also enabled legends to be impressed round the edges of coins, such as the Decus et Tutionem suggested by Evelyn (see J. Hocking, Catalogue of the Coins, &c., in the Museum of the Royal Mint, 1865). It was invented in the middle of the 16th century and has generally been attributed to Guigo de Burguin (d. 1556), who was succeeded at the Paris mint by his brother Antoine. Introduced into England by one Eloye Mestreil in 1561, it was used for twelve years, and was then abandoned owing to the opposition of the mint officials to Mestreil, who was executed for counterfeiting and striking money outside the precincts of the Tower of London; but it was again introduced by one Peter Blondeau in 1662, when it permanently superseded the older methods of hammering. In the United States of America the term "milling" or "milled" is applied to the raised edge on the face of the coin; this is known in the British mint as "marking" (see Mint).

MILLAS, SIR JOHN EVERETT (1829-1866), English painter, was born at Southampton on the 8th of June 1829, the son of John William Millais, who belonged to an old Norman family settled in Jersey for many generations, and Emily Mary, née Evamy, the widow of a Mr Hodgkinson. After his birth the family returned to Jersey, where the boy soon began to sketch. At the age of eight he drew his maternal grandfather. He went to school for a short time, but showed no inclination for study, and was afterwards educated entirely by his mother. In 1835 the family removed to Dinan in Brittany, where he sketched the French officers, to their great amusement, and in 1837, on the family's return to Jersey, he was taught drawing by a Mr Bissel. In 1838 he came to London, and on the strong recommendation of Sir Martin Archer Shee, P.R.A., his future was decided. He was sent at once to Sass's school, and entered the Academy schools in 1840. He won a silver medal from the Society of Arts in 1839, and carried off all the prizes at the Royal Academy. He was popular amongst the students, and was called "the child," because he wore his boyish costume till long after the usual age. In 1840 and the immediately succeeding years he made the acquaintance of Wordsworth and other interesting and useful people. He was at this time painting small pictures, &c., for a dealer named Thomas, and defraying a great part of his expenses by so doing.

In 1846 he exhibited "Pizarro seizing the Inca of Peru" at the Royal Academy, and in 1847 "Elvira seized by the Soldiers of Odo." In the latter year he competed unsuccessfully at the exhibition of designs for the decoration of the Houses of Parliament, sending a very large picture of "The Widow's Mite," which was afterwards cut up. In the beginning of 1848 he and W. Holman Hunt, dissatisfied with the theory and practice of British art, which had sunk to its lowest and most conventional level, initiated what is known as the Pre-Raphaelite movement, and were joined by Dante Gabriel Rossetti, and afterwards by other artists, altogether forming the Pre-Raphaelite Brotherhood. Rossetti was then engaged, under the technical guidance of Hunt, upon his picture of "The Girlhood of Mary Virgin," which, with Hunt's "Light of the World," and Millais's "Christ in the House of His Parents," forms what has been called the trilogy of Pre-Raphaelite art. According to Millais, the Pre-Raphaelites had but one idea—"to present on canvas what they saw in Nature." Millais's first picture on his new principles was a banquet scene from Keats's "Isabella" (1850), and contains all the characteristic elements of Pre-Raphaelite work, including the minute attention to detail, the study of all persons and objects directly from the originals. The tale was told with dramatic force, and the expression of the heads was excellent. His next important picture, "Christ in the House of His Parents," or "The Carpenter's Shop" (1850), represented a supposed incident in the childhood of our Lord treated in a simply realistic manner, and drew upon him a storm of abuse from nearly all quarters, religious and artistic. The rest of his more strictly Pre-Raphaelite pictures—"The Return of the Dove to the Ark," "The Woodman's Daughter," and "The Mariana," of 1851, "The Huguenot" and "Ophelia" of 1852, "The Proscribed Royalist," and "The Order of Release" of 1853—met with less opposition, and established his reputation with the public. Indeed, this may be said to have been accomplished by the "Huguenot" and "Ophelia," the refined sentiment and exquisite execution of which appealed to nearly all who were unprejudiced. The public were also greatly influenced by the splendid championship of Ruskin, who, in letters to The Times, and in a pamphlet on Pre-Raphaelitism, supported the cause of the Brotherhood. In 1851 Millais, who had refused to read Modern Painters, where the supposed principles of the Brotherhood were first recommended, became acquainted with Ruskin, and in 1853 went to Scotland with him and Mrs Ruskin, the latter of whom sat for the woman in "The Order of Release." He made several designs for Ruskin, and painted his portrait. In 1855 Millais exhibited "The Rescue," a scene from a fire, which drew great attention, from the frantic expression of the mother and the brilliant painting of the glare. In the Paris Exhibition of this year he was represented by "The Order of Release," "Ophelia" and "The Return of the Dove." This was also the
year of his marriage with Mrs Ruskin (Euphemia Chalmers, daughter of Mr George Chalmers of Bowerswell, Perth), who had obtained a degree of the nullity of her previous marriage. The newly-wedded couple went to live at Annat Lodge, near Bowerswell, where "Autumn Leaves," described by Ruskin as "the first instance of a perfect twilight," was painted. This and "Peace Concluded" were singled out for special praise by Ruskin in his notes on the Academy Exhibition of 1856, which contained, with other works by Millais, the picture of "A Blind Girl," with a beautiful background of Icklesham and its common. The principal pictures of 1857 were "Sir Isambard the Ford," and "The Escape of a Heretic," both of which were violently attacked by Ruskin, who was kinder to the "Apple-blossoms" and "A Lady of Rest" of 1859, extolling the power of their painting, but still insisting on the degeneracy of the artist. The "Black Brunswicker" of 1860 was in motive very like the "Huguenot," but it was less refined in expression, and a great deal broader in execution, and may be said to mark the end of the period of transition from his minute Pre-Raphaelite manner to the masterly freedom of his mature style. From 1860 to 1869 the invention of Millais was much employed in illustration, especially of Trollope's novels, beginning with "Framley Parsonage" in the "Cornhill Magazine" (1861). In 1868 he published a book of drawings of "London, Westminster, and the South," and in 1870 he was elected a Royal Academician. The most important pictures of this period and the next few years were "The Eve of St Agnes," remarkable for the painting of moonlight, "Romans leaving Britain" (1865), "Jephthah" (1867), "Rosalind and Celia" (1868), "A Flood," and "The Boyhood of Raleigh" (1870). All these were executed in a very broad and masterly manner. In many of his pictures of this period, such as "The Boyhood of Raleigh," his children were his models, and formed the subject of many more, like "My First Sermon," "My Second Sermon," "Sleeping," "Awake," "Sisters," "The First Minuet," and "The Wolf's Den." He now painted many single figures with more or less sentiment, like "Stella," "Vanessa," and "The Gambler's Wife," with occasionally a more important composition, like "Pilgrims to St Paul's," the "Queen Mother's Wardrobe" (exhibited 1878), representing scenes and How building up Moscow Guards (Exod. xvii. 12). With it was exhibited the first and most popular of his pure landscapes, called "Chill October," which was followed at intervals by several others remarkable for literal truth to nature and fine execution. They were all from Perthshire, where he generally spent the autumn, and included "Scotch Fir" and "Winter Fuel" (1874), "Over the Hills and Far Away," and "The Fringe of the Moor" (1875) and "The Sound of Many Waters" (1876). A later series was painted in the neighbourhood of Murthly, a village in the parish of Little Dunkeld, Perthshire, where he rented a house and shooting from 1881 to 1891. It was to painting nature and the world around him that he principally devoted himself for the last twenty-five years of his life, abandoning imaginative or didactic themes. To this period belong a number of pictures of children, with fancy titles, like "Cheery Ripe," "Little Miss Muffet," "Bubbles," and others well known by reproductions in black and white and in colour for the illustrated papers; and also some charming studies of girlhood, like "Swimming" and "The Missing Girl." His most serious pictures were "The Princess in the Tower" (1878), "The Princess Elizabeth" (1879), two pictures from Scott—"Effie Deans" and "The Master of Ravenswood"—painted for Messrs Agnew in 1877 and 1878, and "The North-West Passage," sometimes regarded as his masterpiece, representing an old mariner (painted from Edward John Trelawney, the friend of Byron) listening to some tale of Arctic exploration in a room overlooking the sea and strewed with charts. A Yeoman of the Guard" (1877) was perhaps his most splendid piece of colour, and was greatly admired at the Paris Exhibition of 1878, where it was sent with "Chill October" and three others of his pictures. But perhaps the works of his later years by which he will be most remembered are his portraits—especially his three portraits of Gladstone (1879, 1883 and 1889), and those of John Bright, of Lord Tennyson, and of Lord Beaconsfield, which was left unfinished at his death. He also painted the marquess of Salisbury, Lord Rosebery, the dukes of Devonshire and Argyll, Cardinal Newman, Thomas Carlyle, Sir James Paget, Sir Henry Irving, George Grote, Lord Chief Justice Russell, J. C. Hook, R.A., and himself (Uffizi Gallery, Florence). He drew Charles Dickens after his death. Amongst his finer portraits of women were those of Mrs Bischoffshein, the duchess of Westminster, Lady Campbell and Mrs Jopling.

No very serious interruption of his usual life as a prosperous English gentleman occurred in these years, except the death of his second son, George, in 1878. In 1875 he went to Holland, one of his few visits to the Continent. In 1879 he left Cromwell Place for a house at Palace Gate, Kensington, which he built, and where he died. In 1885 he was created a baronet, on the suggestion of Mr Gladstone. In 1892 his health began to break down. After a bad attack of influenza he was troubled with a swelling in his throat, which proved to be due to cancer. He lived by a large income from his savings, including "St Stephen," "A Disciple," "Speak! Speak!" (which was bought out of the Chantry Bequest), and "The Forerunner"—his last exhibited subject-picture. His finely-characterized portraits of Mr John Hare, the actor, and Sir Richard Quain belong also to his last years. In 1895, in consequence of the illness of Lord (then Sir Frederick) Leighton, he was called upon to preside at the annual banquet of the Royal Academy, and on the death of Lord Leighton he was elected to the presidential chair. He died on the 13th of August 1896, and was buried in St Paul's Cathedral. The Winter Exhibition of the Royal Academy in 1898 was devoted to his works. The list of his honours at home and abroad is a long one. Millais was one of the greatest painters of his time, and did more than any other to infuse a new and healthy life into British art. He had not the imagination of an idealist, but he could paint what he saw with a force which has seldom been excelled. As a man he was manly, frank and genial, devoted to his art and his family, and very fond of sport, especially hunting, fishing and shooting. He was greatly loved by the large circle of friends which he singularly possessed, and had a fine presence. The National Gallery possesses many of his finest works. He is also represented in the National Gallery, in the National Portrait Gallery, the Victoria and Albert Museum, and in the public galleries at Manchester, Liverpool and Birmingham.

MILBURY—MILLENNIUM

rich valley 1200 ft. above the sea surrounded by the spurs of the Levezou, Causee Noir and Larzac ranges. The streets are narrow and some of the houses of great antiquity, but the town is surrounded by spacious boulevards. One of its squares is bordered on two sides by wooden galleries supported on stone columns. The only buildings of special interest are the Romanesque church of Notre Dame, restored in the 15th century, and the fine Gothic belfry of the old hotel de ville. Milburr is seat of a sub-prefect, and possesses tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce and a communal college. The principal industry is the manufacture of gloves, and various branches of the leather industry are carried on. The chief articles of trade are skins, wool, wine and Roquefort cheese.

In the middle ages Milburr was the seat of a viscounty held by the counts of Barcelona and afterwards by the counts of Armagnac. In the 16th century it became one of the leading strongholds of Calvinism in southern France. In 1620 it revolted against Louis XIII., and after its submission Richelieu caused its fortifications to be dismantled. The edict of Nantes hastened the decline of the town, which did not recover its prosperity till after the Revolution.

MILBURY, a township of Worcester county, Massachusetts, on the Blackstone river, 5 m. S.S.E. of Worcester. Pop. (1890), 4428; (1900) 4460; (1905) 4631; (1910) 4740. Area, 1579 sq. m. Milbury is served by the New York, New Haven & Hartford, and the Boston & Albany railways, and by electric interurban railways. It lies for the most part in the valley of the Blackstone river, from which water-power is derived for its mills; among its manufactures are cotton, linen, felt and woollen goods, hemp thread, and foundry and machine-shop products. The municipality owns and operates the waterworks and electric-lighting plant. Milbury was formed in 1813 from the North Parish of Sutton; in 1831 a part of Auburn was annexed to the township.

MILLEDGEVILLE, a city and the county-seat of Baldwin county, in the central part of Georgia, U.S.A., on the Oconee river, at the head of navigation, 52 m. N.E. of Macon. Pop. (1890), 3322; (1900), 4290 (2663 negroes); (1910), 4385. It is served by the Georgia and the Central of Georgia railways. Milledgeville is situated in the Cotton Belt, and its principal industry is the preparation of cotton for the markets. The importance of the place, however, is mainly educational and historical. It is the seat of the Middle Georgia Military and Agricultural College, which occupies the old capitol building, and of the Georgia Normal and Industrial College for girls (1889; enrolment 1908-1909, 653), which is a part of the University of Georgia, and occupies the site of the old state penitentiary. About 2 m. north-west of Milledgeville is the state juvenile reformatory; 2 m. south of the city are the state asylums for white and negro insane; and 3 m. north-west is the state prison farm. Milledgeville was founded in 1803, and was named in honour of John Milledge (1737-1818), a representative in Congress in 1793-1795 and 1795-1802, governor of Georgia in 1796, 1797 and 1798, United States senator in 1806-1809, and a benefactor of the state university. In 1804 it was made the seat of the state government in place of Louisville (capital in 1755-1824; pop. in 1900, 1009), a dignity it held until 1868. The city was first chartered in 1836. Although admirably situated for trade and manufacturing, Milledgeville was surpassed in both by Macon, which became the commercial emporium of middle Georgia; but it was a favourite place of residence for the wealthy and cultivated class of Georgians before the Civil War. It was seized by General William T. Sherman on the 23rd of November 1864. In order to remove the state documents beyond reach of the enemy, Governor Joseph E. Brown called upon the convicts in the penitentiary for aid, granting them pardons in return for their services.

MILLENNIUM (a pseudo-Latin word formed on the analogy of biennium, triennium, from Lat. mille, a thousand, and annus, year), literally a period of a thousand years. The term is specially used of the period of 1000 years during which Christ, as has been believed, would return to govern the earth in person. Hence it is used to describe a vague time in the future when all flaws in human existence will have vanished, and perfect goodness and happiness will prevail. The attribution of a mystic signification to the millennium-period, though perhaps not prominent in that theory of Christian eschatology to which the names Millenarianism and Chiliasm (from Gr. χιλιάς, a thousand) are given, is quite common in non-Christian religions and cosmological systems.

Faith in the nearness of Christ's second advent and the establishing of his reign of glory on the earth was undoubtedly a strong point in the primitive Christian Church. In the anticipations of the future prevalent amongst the early Christians (c. 50-150) it is necessary to distinguish a fixed and a fluctuating element. The former includes (1) the notion that a last terrible battle with the enemies of God was impending; (2) the faith in the speedy return of Christ; (3) the conviction that Christ will judge all men, and (4) will set up a kingdom of glory on earth. To the latter belong views of the Antichrist, of the heathen world-power, of the place, extent, and duration of the earthly kingdom of Christ. These remained in a state of solution; they were modified from day to day, partly because of the changing circumstances of the present by which forecasts of the future were regulated, partly because the indications—real or supposed—of the ancient prophets always admitted of new combinations and constructions. But even here certain positions were agreed on in large sections of Christendom. Amongst these was the expectation that the future kingdom of Christ on earth should have a fixed duration—according to the most prevalent opinion, a duration of one thousand years. From this fact the whole ancient Christian eschatology was known in later times as "chiliasm"—a name which is not strictly accurate, since the doctrine of the millennium was only one feature in its scheme of the future.

1. This idea that the Messianic kingdom of the future on earth should have a definite duration has—like the whole eschatology of the primitive Church—its roots in the Jewish apocalyptic literature, where it appears at a comparatively late period. At first it was assumed that the Messianic kingdom in Palestine would last for ever (so the prophets; cf. Jer. xxiv. 6; Ezek. xxxvii. 25; Joel iv. 20; Dn. vi. 27; Sibyll. iii. 49 seq., 766; Psalt. Salom. xvii. 4; Enoc Lxxi. 14), and this seems always to have been the most widely accepted view (John xii. 34). But from a comparison of prophetic passages of the Old Testament learned apocalyptic writers came to the conclusion that a distinction must be drawn between the earthly appearance of the Messiah and the appearance of God Himself amongst His people and in the Gentile world for the final judgment. As a necessary consequence, a limited period had to be assigned to the Messianic kingdom. According to the Apocalypse of Baruch (xl. 3) this kingdom will last "donec finiatur mundus corruptionis." In the Book of Enoch (xci. 11) "a week" is specified, in the Apocalypse of Ezra (vii. 28 seq.) four hundred years. This figure, corresponding to the four hundred years of Egyptian bondage, was also in the Talmud (Sanhedrin 99b). But this is the only passage; the Talmud has not preserved the larger view most frequently expressed there (see Von Otto in Hilgenfeld's Zeitschrift, 1877, p. 527 seq.) that the Messianic kingdom will last for one thousand (some said two thousand) years. "In six days God created the world, on the seventh He rested. But a day of God is equal to a thousand years (Ps. xc. 4). Hence the world will last for six thousand years of toil and labour; then will come one thousand years of Sabbath rest for the people of God in the kingdom of the Messiah." This idea must have already been very common in the first century before Christ. The combination of Gen. iii, Dan. ix. and Ps. xc. 4 was peculiarly fascinating.

Nowhere in the discourses of Jesus is there a hint of a limited duration of the Messianic kingdom. The apostolic epistles are equally free from any trace of chiliasm (neither 1 Cor. xv. 23 seq. nor 1 Thess. iv. 16 seq. points in this direction). In Revelation however, it occurs in the following shape (ch. xx.). After
Christ has appeared from heaven in the guise of a warrior, and vanquished the antichristian world-power, the wisdom of the world and the devil, those who have remained steadfast in the time of the last catastrophe, and have given up their lives for their faith, shall be raised up, and shall reign with Christ on this earth as a royal priesthood for one thousand years. At the end of this time Satan is to be let loose again for a short season; he will prepare a new onslaught, but God will miraculously destroy him and his hosts. Then will follow the general resurrection of the dead, the last judgment, and the creation of new heavens and a new earth. That all believers will have a share in the first resurrection and in the Messianic kingdom is an idea of which the author of Revelation knows nothing. The earthly kingdom of Christ is reserved for those who have endured the most terrible tribulation, who have withstood the supreme effort of the world-power—that is, for those who are actually members of the church of the last days. The Jewish expectation is thus considerably curtailed, as it is also shorn of its sensual attractions. Blessed and holy is he that hath part in the first resurrection; on such the second death hath no power; but they shall be priests of God and of Christ, and shall reign with Him a thousand years. "Other ancient Christian authors were not so cautious. Accepting the Jewish apocalypses as sacred books of venerable antiquity, they read them eagerly, and transferred their contents bodily to Christianity. Nay more, the Gentile Christians took possession of them, and just in proportion as they were neglected by the Jews—who, after the war of Bar-Cochba, became indifferent to the Messianic hope and hardened themselves once more in devotion to the law—that they were naturalized in the Christian communities. The result was that these books became "Christian" documents; it is entirely to Christian, not to Jewish, tradition that we owe their preservation. The Jewish expectations are adopted for example, by Papias, by the writer of the epistle of Barnabas, and by Justin. Papias actually confounds expressions of Jesus with verses from the Apocalypse of Baruch, referring to the amazing fertility of the days of the Messianic kingdom (Papias, vita I., 4). Barnabas (Ep. 15) gives us the Jewish theory (from Gen. i. and Ps. xc. 4) that the present condition of the world is to last six thousand years from the creation, that at the beginning of the Sabbath (the seventh millennium) the Son of God appears, to put an end to the time of "the unjust one," to judge the ungodly and renew the earth. But he does not indulge, like Papias, in sensuous descriptions of this seventh millennium; to Barnabas it is a time of rest, of sinlessness, and of a holy peace. It is not the end, however; it is followed by an eighth day of eternal duration— "the beginning of another world." So that in the view of Barnabas the Messianic reign still belongs to oistros ὃ ἄνων. Justin (Dial. 80) speaks of chiliasm as a necessary part of complete orthodoxy, although he knows Christians who do not accept it. He believes, with the Jews, in a restoration and extension of the city of Jerusalem; he assumes that this city will be the seat of the Messianic kingdom, and explains that this is a matter of temporal blessedness; that all believers (here he is at one with Barnabas) along with patriarchs and prophets will enjoy perfect felicity for one thousand years. That a philosopher like Justin, with a bias towards an Hellenic construction of the Christian religion, should nevertheless have accepted its chilastic elements is the strongest proof that these enthusiastic expectations were inseparably bound up with the Christian faith down to the middle of the 2nd century. And another proof is found in the fact that even a speculative Jewish Christian like Cerinthus not only did not renounce the chilastic hope, but pictured the future kingdom of Christ as a kingdom of sensual pleasures, of eating and drinking and marriage festivities (Euseb. H. E. iii, 28, vii, 25).

After the middle of the 2nd century these expectations were gradually thrust into the background. They would never have died out, however, had not circumstances altered, and a new mental attitude been taken up. The spirit of philosophical and theological speculation and of ethical reflection, which began to spread through the churches, did not know what to make of the old hopes of the future. To a new generation they seemed paltry, earthly and fantastic, and far-seeing men had good reason to regard them as a source of political danger. But more than this, these wild dreams about the glorious kingdom of Christ began to disturb the organization which the churches had seen fit to introduce. In the interests of self-preservation against the world, the state and the heretics, the Christian communities had formed themselves into compact societies with a definite creed and constitution, and they felt that their existence was threatened by the white heat of religious subjectivity. So early as the year 170, a church party in Asia Minor—the so-called Alogi—rejected the whole body of apocalyptic writings and denounced the book of Revelation as a book of fables. All the more powerful was the reaction. In the so-called Montanistic controversy (c. 160–220) one of the principal issues involved was the continuance of the chilastic expectations in the churches. The Montans of Asia Minor defended them in their integrity, with one slight modification: they announced that Pupza, the city of Montanus, would be the site of the New Jerusalem and the millennial kingdom. After the Montanistic controversy chilastic views were more and more discredited in the Greek Church; they were, in fact, stigmatized as "Jewish" and consequently "heretical." It was the Alexandrian theology that superseded them; that is to say, Neo-Platonic mysticism triumphed over the early Christian hope of the future, first among the "cultured," and then, when the theology of the "cultured" had taken the faith of the "uncultured" under its protection, amongst the latter also. About the year 260 an Egyptian bishop, Nepos, in a treatise called ἔγχως ἀληθευτοῦ, endeavoured to overthrow the Originistic theology and vindicate chiliasm by exegetical methods. Several congregations took his part; but ultimately Dionysius, bishop of Alexandria, in a treatise called Προτάσσων Ἰησοῦν ἀνοιχτὰ the Alexandrian theology that superseded them; that is to say, Neo-Platonic mysticism triumphed over the early Christian hope of the future, first among the "cultured," and then, when the theology of the "cultured" had taken the faith of the "uncultured" under its protection, amongst the latter also. About the year 260 an Egyptian bishop, Nepos, in a treatise called ἔγχως ἀληθευτοῦ, endeavoured to overthrow the Originistic theology and vindicate chiliasm by exegetical methods. Several congregations took his part; but ultimately Dionysius, bishop of Alexandria, succeeded in healing the schism and asserting the allegorical interpretation of the prophets as the only legitimate exegesis. During this controversy Dionysius became convinced that the victory of mystical theology over "Jewish" chiliasm would never be secure so long as the book of Revelation passed for an apostolic writing and kept its place among the homologumena of the canons. He therefore raised the question of its apostolic origin; and by reviving old difficulties, with ingenious arguments of his own, he carried his point. At the time of Eusebius the Greek Church was saturated with prejudice against the book and with doubts as to its canonicity. In the course of the 4th century it was removed from the Greek canon, and thus the troublesome foundation on which chiliasm might have continued to build was got rid of. The attempts of Methodius of Tyre at the beginning of the 4th century and Apollinaris of Laodicea about 360 to defend chiliasm and assail the theology of Origen had no result. For many centuries the Greek Church kept Revelation out of its canon, and consequently chiliasm remained in its grave. It was considered a sufficient safeguard against the spiritualizing eschatology of Origen and his school to have rescued the main doctrines of the creed and the regulæ fidei (the visible advent of Christ; eternal misery and hell-fire for the wicked). Anything beyond this was held to be "Jewish." It was only the chroniclers and historians of the church who, following Julius Africanus, made use of apocalyptic numbers in their calculations, while court theologians like Eusebius entertained the imperial table with discussions as to whether the dining-hall of the emperor—the second David and Solomon, the beloved of God—might not be the New Jerusalem of John's Apocalypse. Eusebius was not the first who dabbled in such speculations. Dionysius of Alexandria had already referred a Messianic prediction of the Old Testament to the emperor Gallienus. But mysticism and political servility between them gave the death-blow to chiliasm in the Greek Church. It never again obtained a footing there; for, although, late in the middle ages, the book of Revelation—by what means we cannot tell—did recover its authority, the Church was by that time so hopelessly trammeled by a magical cultus as to be incapable of fresh developments. In the Semitic churches of the East (the Syrian, Arabian and Ethiopian), and in that of Armenia, the apocalyptic literature was preserved much longer than in the Greek Church. They were very conservative of ancient traditions in general, and hence
chiliasm survived amongst them to a later date than in Alexandria or Constantinople.

But the Western Church was also more conservative than the Greek. Her theologians had, to begin with, little turn for mystical speculation; their tendency was rather to sacralize the gospel to a system of morals. Now for the moralists chiliasm had a special significance as the one distinguishing feature of the gospel, that simple thing that gave a specifically Christian character to their system. This, however, holds good of the Western theologians only after the middle of the 3rd century. The earlier fathers, Irenaeus, Hippolytus, Tertullian, believed in chiliasm simply because it was a part of the tradition of the church and because Marcion and the Gnostics would have nothing to do with it. Irenaeus (v. 28, 29) has the same conception of the millennial kingdom as Barnabas and Papias, and appeals in support of it to the testimony of disciples of the apostles. Hippolytus, although an opponent of Montanism, was nevertheless a thorough-going millenarian (see his book De Antichristo). Tertullian (cf. especially Adv. Macion., 3) aimed at a more spiritual conception of the millennial blessings than Papias had, but he still adhered, especially in his Montanistic period, to all the ancient anticipations. It is the same all through the 3rd and 4th centuries with those Latin theologians who escaped the influence of Greek speculation. Commodian, Victorinus Peta- vensis, Lactantius and Sulpicius Severus were all pronounced millenarians, holding by the very details of the primitive Christian expectations. They still believe, as John did, in the return of Nero as the Antichrist; they still expect that after the first resurrection Christ will reign with his saints “in the flesh” for a thousand years. Once, but only once (in the Gospel of Nicodemus), the time is reduced to five hundred years. Victorinus wrote a commentary on the Apocalypse of John; and all these theologians, especially Lactantius, were diligent students of the ancient Sibylline oracles of Jewish and Christian origin, and treated them as divine revelations. As to the canonicity and apostolic authorship of the Johannine Apocalypse no doubts were ever entertained in the West; indeed an Apocalypse of Peter was still retained in the canon in the 3rd century. That of Ezra, in its Latin translation, must have been all but a canonical book—the numbers of extant manuscripts of the so-called 4 Ezra being incredibly great, while several of them are found in copies of the Latin Bible at the beginning of the 16th century. The Apocalypse of Hermas was much read till far through the middle ages, and has also kept its place in some Bibles. The apocalyptic “Testamenta duodecim patriarcharum” was a favourite reading-book; and Latin versions of ancient apocalypses are being continually brought to light from Western libraries (e.g. the Assumption Mosis, the Ascensio Jesu, etc.). All these facts show how vigorously the early hopes of the future maintained themselves in the West. In the hands of moralistic theologians, like Lactantius, they certainly assume a somewhat grotesque form, but the fact that these men clung to them is the clearest evidence that in the West millenarianism was still a point of “orthodoxy” in the 4th century.

This state of matters, however, gradually disappeared after the end of the 4th century. The change was brought about by two causes—first, Greek theology, which reached the West chiefly through Jerome Rufinus and Ambrose, and, second, the new idea of the church wrought out by Augustine on the basis of the altered political situation of the church. Augustine was the first who ventured to teach that the catholic church, in its empirical form, was the kingdom of Christ, that the millennial kingdom had commenced with the appearing of Christ, and that therefore was an accomplished fact. By this doctrine of Augustine’s, the old millenarianism, though not completely extinguished, was at least banished from the official theology. It still lived on, however, in the lower strata of Christian society; and in certain undercurrents of tradition it was transmitted from century to century. At various periods in the history of the Middle Ages we encounter sudden outbreaks of millenarianism, sometimes as the tenet of a small sect, sometimes as a far-reaching movement. And, since it had been suppressed, not, as in the East, by mystical speculation, its mightiest antagonist, but by the political church of the hierarchy, we find that wherever chiliasm appears in the middle ages it makes common cause with all enemies of the secularized church. It strengthened the hands of church democracy, it formed in alliance with the pure souls who held on to the church the ideal of apostolic poverty; it united itself for a time even with mysticism in a common opposition to the supremacy of the church; nay, it lent the strength of its convictions to the support of states and princes in their efforts to break the political power of the church. It is sufficient to recall the well-known names of Joachim of Floris, of all the numerous Franciscan spiritualists, of the leading sectaries from the 13th to the 15th century who assailed the papacy and the secularism of the church—above all, the name of Occam. In these men the millenarianism of the ancient church came to life again; and in the revolutionary movements of the 15th and 16th centuries—especially in the Anabaptist movements—it appears with all its old uncompromising energy. If the church, and not the state, was regarded as Babylon, and the pope declared to be the Antichrist, these were legitimate inferences from the ancient traditions and the actual position of the church. But, of course, the new chiliasm was not in every respect identical with the old. It could not hold its ground without admitting certain innovations. The “everlasting gospel” of Joachim of Floris was a different thing from the announcement of Christ’s glorious return in the clouds of heaven; the “age of the spirit” in which mystics and spiritualists expected constant contact with the Christ who had “contracted his kingdom” and the “kingdom” of the Anabaptists in Münster was a Satanic caricature of that kingdom in which the Christians of the 2nd century looked for a peaceful Sabbath rest. Only we must not form our ideas of the great apocalyptic and chiliastic movement of the first decades of the 16th century from the rabble in Münster. There were pure evangelical forces at work in it; and many Anabaptists need not shun comparison with the Christians of the apostolic and post-apostolic ages.

The German and Swiss Reformers also believed that the end of the world was near, but they had different aims in view from those of the Anabaptists. It was not from poverty and apo- lymphaticism that they hoped for a reformation of the Church. In contrast to the fanatics, after a brief hesitation they threw millenarianism overboard, and along with it all other “opiniones Judaicae.” They took up the same ground in this respect which the Roman Catholic Church had occupied since the time of Augustine. How millenarianism nevertheless found its way, with the help of apocalyptic mysticism and Anabaptist influences into the churches of the Reformation, chiefly among the Reformed sects, but afterwards also in the Lutheran Church, how it became incorporated with Pietism, how in more recent times an exceedingly mild type of “academic” chiliasm has been developed from a belief in the verbal inspiration of the Bible, how finally new sects are still springing up here and there with apocalyptic and chiliastic expectations—these are matters which cannot be fully entered upon here.

(A. H.)

Miller, Hugh (1802–1856), Scottish geologist and man of letters, was born in humble circumstances in Cumnock, on the roth of October 1822. He was the son of Hugh Miller, a seaman, who died when he was but five years old. His primary education was acquired at a dame’s school and afterwards at the parish school, and at the age of six he had learned that “the art of reading is the art of finding stories in books.” At the age of twelve he began to write verses. Two of his mother’s brothers, James and “Sandy” Wright, hard-working men at Cumnock,
Miller, Joaquin—Miller, W.

His elder son, Hugh Miller (1850–1896), passed through the Royal School of Mines and joined the Geological Survey in England in 1873; afterwards he was transferred to Scotland and surveyed the country around Cromarty and various other parts of Ross-shire and Sutherlandshire. He was admitted as a member of the Geological Society of Edinburgh, and was elected a fellow in 1889.

Miller, Josiah (1850–1896), American poet, was born in Indiana, on the 10th of November 1841, and was educated for the law. After some experiences of mining and journalism in Idaho and Oregon, he settled down in 1866 as judge in Grant county, Oregon, and during his four years' tenure of this post he began to write verse. In 1870 he travelled in Europe, and in 1871 he published his first volume of poetry, full of tropical passion, Songs of the Sierras, on which his reputation mainly rests. His Songs of the Sunlands (1873) followed in the same vein, and after other volumes had appeared, his Collected Poems were published in 1882. He also wrote plays, The Danites in the Sierras having some success as a sensational melodrama. On his return from Europe he became a journalist in Washington, and in 1887 returned to California. His pen-name, "Joaquin Miller," by which he is known, was assumed by him when he published his first book, in consequence of his having written an article in defence of Joaquin Murieta, the Mexican brigand.

Revised editions of his Complete Poetical Works appeared at San Francisco in 1902.

Miller, Samuel Freeman (1816–1890), American jurist, was born in Richmond, Kentucky, on the 5th of April 1816, of Pennsylvania-German stock. He was brought up on a farm, was a clerk in a drug-store, graduated from the medical department of Transylvania University in 1838, and practised medicine in Barbourville, Kentucky, until 1847. In that year he was admitted to the bar, and entered politics as a Whig. His anti-slavery sympathies induced him to settle in Iowa, where in 1850 he freed his slaves and began to practise law in Keokuk, and he soon became a leader of the Republican party in the state. In 1862 he succeeded Justice Peter V. Daniel (1784–1864), as a justice of the U.S. Supreme Court, and served until his death in Washington, D.C., on the 13th of October 1890, when he was senior justice. Miller was a man of great mental force and individuality, and his judgments carried great weight. In 1867 he was a member of the electoral commission, which adopted his motion that Congress could not “go behind the returns” as properly accredited by state officials. He was a prominent member of the United Church and for three years was president of its national conference. He published a volume of Lectures on the Constitution of the United States (New York, 1891).

Miller, William (1782–1849), leader of the Second Adventists in America, was born on the 5th of February 1782 at Pittsfield, Massachusetts. He was a recruiting officer at the beginning of the War of 1812, and after Plattsburg he was promoted captain, retiring from the army in 1815. About 1816 he settled in Low Hampton, Washington county, New York.
MILLER, W.—MILLERITE

He now joined the Baptist Church at Low Hampton, and, after two years of minute study of the Bible, about 1818 became a Second Adventist. In 1831 he began to lecture, arguing that the "two thousand three hundred days" of Daniel viii. 14 meant 2300 years, and that these years began with Ezra's going up to Jerusalem in 457 B.C. He then went to an end in 1843, and urged his hearers to make ready for the final coming of Christ in that year. To his many followers, after the year 1843 had passed, he proclaimed that 1843 was the year, that his error was due to following Hebrew instead of Roman chronology, and that the 22nd of October was to be the day. There was renewed excitement among Miller's followers; many of them left their business, and in white muslin robes, on house tops and hills, awaited the epiphany. In spite of disappointment, many still believed with him that the time was near. He returned to Low Hampton and died there on the 20th of December 1849. The Adventists or Millerites, who were formed into a single body in a convention called by him in April 1845, have since separated into several sects: the Evangelical Adventists (1847 in the United States in 1848), who believe in everlasting punishment; the Seventh Day Adventists (64,332), who observe the seventh day, and practice the sacrament of foot-washing; the Advent Christians (56,500), the Churches of God in Jesus Christ (2872), and the Life and Advent Union (3800). Their total number in the United States in 1908 was about 99,300. Miller published in 1833 a pamphlet which was the basis of his lectures; these were published in 1842 as Evidence from Scripture and History of the Second Coming of Christ about the Year 1843.

See Sylvester Bliss, Memoirs of William Miller (Boston, 1853); James White, Sketches of the Christian Life and Public Labors of William Miller (Liffield Bank, 1875); and Edward Eggleston's novel, End of the World (1872).

MILLER, WILLIAM (1792–1861). British soldier, who took a prominent part in the South American Wars of Liberation, entered the British artillery service in 1811, and in 1814 he was continuously on active service with Wellington's army in the Peninsula. In the latter year he accompanied the ill-fated New Orleans expedition. After the general peace he travelled for two years about Europe, and then went to South America. The war which culminated in the expulsion of the Spaniards was just breaking out, and he took command in the Chilean artillery, with which he served during the Chilean part of the war. As a major he commanded the marines on Cochrane's vessel, the "O'Higgins." In 1821 he landed in Peru, to assist General San Martin against the Spanish General Canterac. He was made general of brigade, and became very intimate with Simon Bolivar. He rendered the most conspicuous services at Junin (Aug. 6, 1824), and his regiment, the "Hussars of Junin," covered itself with glory in the decisive victory of Ayacucho (Dec. 9, 1824). From 1825 to 1830 he filled various high military and political offices in Peru. In the latter year he was invited to the fall of Santa Cruz, and went into exile. For some years he filled the post of British Consul-General of the Pacific Coast. He died on board H.M.S. "Naiad" at Callao, on the 31st of October 1861. See the Memoirs published by his brother John Miller (London, 1827).

MILLER, WILLIAM (1796–1888), Scottish line-engraver, was born in Edinburgh on the 28th of May 1796. After studying in London under George Cook, a pupil of Basire's, he returned to Edinburgh. He executed plates after Thomson of Duddingston, Macculloch, D. O. Hill, Sir George Harvey, and other Scottish landscapists, but his chief works were his transcripts from Turner. The first of these was the Clavelly (1824), of The Southern Coast, a publication undertaken by George Cook and his brother William B. Cook, to which Miller also contributed the Combe Martin and the Portsmouth. He was engaged on the illustrations of England and Wales, 1827–1838; of The Rivers of France, 1833–1835; of Roger's Poems, 1834; and very largely on those of The Prose and Poetical Works of Sir Walter Scott, 1834. In The Provincial Antiquities and Picturesque Scenery of Scotland, 1826, he executed a few excellent plates after Thomson and Turner. Among his larger engravings of Turner's works may be mentioned "The Grand Canal, Venice," "The Rhine, Osterey and Felzien," "The Bell Rock," "The Tower of London," and "The Shepherd." The death of William Miller was warmly appreciated by Turner himself, and Ruskin pronounced him to be on the whole the most successful translator into line of the paintings of the greatest English landscapist. His renderings of complex Turnerian sky-effects are especially delicate and masterly. Towards the end of his life Miller abandoned engraving and occupied his leisure in the production of water-colours, many of which were exhibited in the Royal Scottish Academy, of which he was an honorary member. He resumed his burin, however, to produce two final series of vignettes from drawings by Birket Foster illustrative of Hood's Poems, published by Moxon in 1871. Miller, who was a Quaker, died on the 20th of January 1882.

MILLER, WILLIAM HALLOWES (1801–1880), British mineralogist and crystallographer, was born at Velindre near Llandovery, Carmarthenshire, on the 6th of April 1801. He was educated at St John's College, Cambridge, where he graduated in 1826 as fifth wrangler, and became a fellow in 1829. For a few years he was occupied as a college tutor and during this time he published treatises on hydrostatics and hydrodynamics. He showed special attention to crystallography, and on the resignation of W. Whewell he succeeded in 1842 to the professorship of mineralogy, a post which he occupied until 1870. His chief work, on Crystallography, was published in 1838. He was elected F.R.S. in 1838. In 1852 he edited a new edition of H. J. Brooke's Elementary Introduction to Mineralogy. He assisted in 1843 the committee appointed to superintend the construction of the new Parliamentary standards of length and weight (see Phil. Trans., 1856). He died in Cambridge on the 20th of May 1880.

MILLERAND, ALEXANDRE (1899– ), French socialist and politician, was born in Paris on the 10th of February 1859. He was educated for the bar, and made his reputation by his defence, in company with Georges Laguerre, of Ernest Reche and Duc-Quercy, the instigators of the strike at Decazeville in 1883; he then took Laguerre's place on M. Clemenceau's paper, La Justice. He was elected to the Chamber of Deputies for the department of the Seine in 1885 as a radical socialist. He was associated with M.M. Clemenceau and Camille Pellatian as an arbitrator in the Carmaux strike (1892). He had long had the ear of the Chamber in matters of social legislation, and after the Panama scandals had discredited so many politicians his influence grew. He was chief of the Socialist left, which then mustered sixty members, and edited until 1896 their organ in the press, La Petite République. His programme included the collective ownership of the means of production and the international association of labour, but when in June 1899 he entered Waldeck-Rousseau's cabinet of "republican defence" as minister of commerce he limited himself to practical reforms, devoting his attention to the improvement of the mercantile marine, to the development of trade, of technical education, of the postal system, and to the amelioration of the conditions of labour. Labour questions were entrusted to a separate department, the Direction du Travail, and the pension and insurance office was turned into the status of a "direction." The introduction of trades-union representatives on the Supreme Labour Council, the organization of local labour councils, and the instructions to factory inspectors to put themselves in communication with the councils of the trades-unions, were valuable concessions to labour, and he further secured the rigorous application of earlier laws devised for the protection of the working-classes. His name was especially associated with a project for the establishment of old age pensions, which became law in 1905. He became in 1898 editor of La Lanterne. His influence with the extreme Socialists had already declined, for it was said that his departure from the true Marxist tradition had disintegrated the party.

For his administration in the Waldeck-Rousseau cabinet see A. Lavy, L'Oeuvre de Milleraud (1902); his speeches between 1899 and 1907 were published in 1907 as Travail et travailleurs.

MILLERITE, a mineral consisting of nickel sulphide, NiS. Crystals belong to the rhombohedral system and have the form
MILLER'S THUMB—MILLET, J. F.

of slender needles arranged in divergent groups or of delicate fibres loosely matted together. The colour is brass-yellow and the lustre metallic. Before the chemical composition of the mineral had been determined it had been known as “capillary pyrites” or “hair pyrites” (Ger., Haarknister), and was not distinguished from the capillary forms of pyrites and marcasite: the name millerite was given by W. Haidinger in 1845, in honour of W. H. Miller. The hardness is 3-33 and the specific gravity 5-65. There are perfect cleavages parallel to the faces of the rhombohedron (100); and gliding planes parallel to the faces of the rhombohedron (110), on which secondary twinning may be readily produced artificially by pressure.

Typical specimens of millerite are found in the coal measure in the neighbourhood of Meryth Tydfil in South Wales, where the delicate needles and fibres occur with crystals of quartz and pyrites; and in the fissures of septarian nodule of claystone. Radiating groups of needles are found with ankerite in cavities in haematitic in the Sterling mine at Antwerp in Jefferson county, New York. At the Gap mine in Lancaster county, Pennsylvania, the mineral occurs as fibrous euhedral masses with a cloudy lustre. The most perfect crystals are those formerly found with calcite, diopside and a bright green chrome-garnet in a nickel mine at Orford in Sherbrooke county, Quebec.

MILLER'S THUMB (Cottus gobio), a small fish, abundant in all rivers and lakes of northern and central Europe with clear water and gravely bottom. The genus Cottus, to which the miller's thumb belongs, is easily recognized by its broad, flat head, rounded and scaleless body, large pectoral and parallel ventral fins, with two dorsal fins, the anterior shorter than the posterior; the praecocerulum is armed with a single or branched spine. The species of the genus Cottus are rather numerous, and are confined to the north temperate zone of the globe, the majority being marine, and known by the name of “bullheads.” The miller's thumb is confined to fresh water, and only one other freshwater species is found in England, C. pocelopus, from rivers in Hanover, Galicia, and the Pyrenees; sometimes occurring in the fresh waters of northern Asia and North America. The miller's thumb is common in all suitable localities in Great Britain, but is extremely rare in Ireland; in the Alps it reaches an altitude exceeding 7000 ft. Its usual length is from 3 to 5 in. Generally hidden under a stone or in a hollow of the bank, it watches for its prey, which consists of small aquatic animals, and darts when disturbed with extraordinary rapidity to some other place of refuge. The female deposits her ova in a cavity under a stone, whilst the male watches and defends them until the young are hatched and able to shift for themselves.

MILLET, FRANCIS DAVIS (1846–1908), American artist, was born at Mattapoisett, Massachusetts, on the 3rd of November 1846. He was a drummer boy with the Union forces in the Civil War; graduated from Harvard College in 1869; and in 1871 entered the Royal Academy at Antwerp, where he studied under Varin, Dujet and De Keyser. In 1873 he was made secretary of the Massachusetts commission to the Vienna Exhibition. During the Russo-Turkish War of 1877–78 he was correspondent of the London Daily News and Graphic, and of the New York Herald. On his return he was made a member from the United States of the International Art Jury at the Paris Exhibition of 1878. He was director of decorations at the Columbian Exposition, Chicago, 1893, and in 1898 he went to Manila as war correspondent for The Times and for Harper's Weekly. In 1886 he became a member of the Society of American Artists, and in 1885 was elected to full membership in the National Academy of Design, New York, and was for one term its vice-president; he became a member also of the American Water Color Society and of the Institute of Painters in Oil Colours, London. As a decorative artist his work may be seen at Trinity Church, Boston; the Bank of Pittsburgh, and the Capitol at St Paul, Minnesota. His pictures are in many public collections: among them are “A Cosy Corner,” in the Metropolitan Museum of Art, New York; “At the Inn,” in the Union League Club, New York; and “Between two Fires,” in the Tate Gallery, London. He also wrote essays and short stories, and an English version of Tolstoy's Sebastopol (1887); and among his publications are The Donau (1891), Capillary Crime and other Stories (1892), and Expedition to the Philippines (1890).

MILLET (or Milà), JEAN FRANÇOIS (c. 1642–1709), commonly called Francisque, was born at Antwerp about 1642, and is generally classed amongst the painters of Flanders on account of the accident of his birth. But his father was a Frenchman, a turner in ivory of Dijon, who took service with the prince of Condé and probably returned after a time to his native country. He remained long enough in Antwerp to apprentice his son to an obscure member of a painter family called Laurent, pupil of Gabriel Franck. With Laurent, Francisque left Antwerp for Paris, and there settled in 1660 after marrying his master’s daughter. He was received a member of the Academy of Painting at Paris in 1673, and after gaining consideration as an imitator of the Poussins he died in 1679, bequeathing his art and some of his talents to one of his sons. Francisque probably knew, as well as imitated, Nicolas Poussin, Gaspar Duguet and Sebastian Bourdon; and it is doubtful because of his acquaintance with these travelled artists that, being himself without familiarity with the classic lands of Italy and Greece, he was able to imagine and reproduce Italian and Arcadian scenery with considerable grace and effectiveness. It is indeed surprising to observe, even at this day how skilfully he executed these imaginary subjects, enlivened them with appropriate figures, and shed over them the glow of a warm yet fresh and sparkling tone. Twelve of his most important landscapes, which remained in the palace of the Tulleries, were destroyed by fire; and though many of his pieces may still be found catalogued in Continental and English collections, others in great number remain unknown and unacknowledged.

His son, JEAN FRANÇOIS MILLET, the younger (1666–1723), was born in Paris, and was made a member of the Academy of Painting in 1709. He is not so independent in his art as his father; but he had clever friends, and when he wanted figures to his landscapes, he consulted Watteau, and other followers of the “court shepherdess” school. In the museum of Grenoble is a “Paysage” by him which is pretty adorned with Watteau's figures.

MILLET, JEAN FRANÇOIS (1814–1875), French painter, who came of a peasant family, was born on the 4th of October 1814 in the hamlet of Gruchy, near Gréville (La Manche), in the wild and picturesque district called La Hague. His boyhood was passed working in his father's fields, but the sight of the engravings in an old illustrated Bible set him drawing, and thenceforth, whilst the others slept, the daily hour of rest was spent by Millet in trying to render the familiar scenes around him. From the village priest the lad learnt to read the Bible and Virgil in Latin, and acquired an interest in one or two other works of a high class which accompanied him through life; he did not, however, attract attention so much by his acquirements as by the stamp of his mind. The whole family seems, indeed, to have worn a character of austerity and dignity, and when Millet's father finally decided to test the vocation of his son as an artist, it was with a gravity and authority which recalls the patriarchal households of Calvinist France. Two drawings were prepared and placed before a painter at Cherbourg named Mouchel, who at once recognized the boy's gifts, and accepted him as a pupil; but shortly after (1835) Millet's father died, and the eldest son, with heroic devotion, took his place at home, nor did he return to his work until the pressing calls from without were solemnly enforced by the wishes of his own family. He accordingly went back to Cherbourg, but after a short time spent there with another master (Langois) started with many misgivings for Paris. The council-general of the department had granted him a sum of 600 francs, and the town council promised an annual pension of 400, but in spite of friendly help and introductions Millet went through great difficulties. The system of the École des Beaux Arts
was hateful to him, and it was not until after much hesitation that he decided to enter an official studio—that of Delaroche. The master was absolutely puzzled by his pupil; he saw his ability, and, while Millet in his poverty could not longer pay the monthly fees, arranged for his free admission to the studio, but he tried in vain to make him take the approved direction, and lessons ended with "Eh, bien, allez à votre guise, vous êtes si nouveau pour moi que je ne veux rien vous dire." At last, when the competition for the Grand Prix came on, Delaroche gave Millet to understand that he intended to secure the nomination of another, and thereupon Millet withdrew himself, and with his friend Marolle started in a little studio in the Rue de l'Est. He had renounced the beaten track, but he continued to study hard whilst he sought to procure bread by painting portraits at 10 or 15 francs apiece and producing small "pastiches" of Watteau and Boucher. In 1840 Millet went back to Gréville, where he painted "Sailors Mending a Sàil" and a few other pictures—reminiscences of Cherbourg life.

His first success was obtained in 1844, when his "Milkwoman" and "Lesson in Riding" (pastel) attracted notice at the Salon, and friendly artists offered themselves at his lodgings only to find that his wife had just died, and that he himself had disappeared. Millet was at Cherbourg; there he remained, but having amassed a few hundred francs he went back to Paris and presented his "St Jerome" at the Salon of 1845. This picture was rejected and exists no longer, for Millet, short of canvas, painted over it "Oedipus Unbound," a work which during the following year was the object of violent criticism. He was, however, no longer alone; Diaz, Eugène Tournoux, Rousseau, and other men of note supported him by their confidence and friendship, and he had by his side the brave Catherine Lemaire, his second wife, a woman who bore poverty with dignity and gave courage to her husband through the cruel trials in which he penetrated by a terrible personal experience the bitter secrets of the very poor. To this date belong Millet's "Golden Age," "Bird Nesters," "Young Girl and Lamb," and "Bathers," but to the "Bathers" (Louvre) succeeded "The Mother Asking Alms," "The Workman's Monday," and "The Winnowers." This last work, exhibited in 1848, obtained conspicuous success, but did not sell till Ledru Rollin, informed of the painter's dire distress, gave him 500 francs for it, and accompanied the purchase with a commission, the money for which enabled Millet to leave Paris for Barbizon, a village on the skirts of the forest of Fontainebleau. There he settled in a three-roomed cottage for the rest of his life—twenty-seven years, in which he wrought out the perfect story of that peasant life of which he alone has given a "complete impression." Jules Breton has coloured the days of toil with sentiment; others, like Courbet, whose eccentrcic "Funeral at Ornans" attracted more notice at the Salon of 1850 than Millet's "Sowers and Binders," have treated similar subjects as a vehicle for protest against social misery; Millet alone, a peasant and a miserable one himself, saw true, neither softening nor exaggerating what he saw. In a curious letter written to M. Senier at this time, Millet expressed his resolve to break on with all by mythological and undraped subjects, and the names of the principal works painted subsequently will show how steadfastly this resolution was kept. In 1852 he produced "Girls Sewing," "Man Spreading Manure"; 1853, "The Reapers"; 1854, "Church at Gréville"; 1855—the year of the International Exhibition, at which he received a medal of second class—"Peasant Grafting a Tree"; 1857, "The Gleaners"; 1859, "The Angelus," "The Woodcutter and Death"; 1860, "Sheep Shearing"; 1861, "Woman Shearing Sheep," "Woman Feeding Child"; 1862, "Potato Planters," "Winter and the Crows"; 1865, "Man with Hoe," "Woman Carding"; 1864, "Shepherds and Flock, Peasants Bringing Home a Calf Born in the Fields"; 1869, "Knitting Lesson"; 1870, "Buttermaking; 1871, "November—recollection of Gruchy." Any one of these works will show how great an influence Millet's previous practice in the nude had upon his style. The dresses worn by his figures are not clothes, but drapery through which the forms and movements of the body are strongly felt, and their contour shows a grand breadth of line which strikes the eye at once. Something of the imposing unity of his work, was also, no doubt, due to an extraordinary power of memory, which enabled Millet to paint (like Horace Vernet) without a model; he could recall with precision the smallest details of attitudes or gestures which he proposed to represent. Thus he could count on presenting free from afterthoughts the vivid impressions which he had first received, and Millet's nature was such that the impressions which he received were always of a serious and often of a noble order, to which the character of his execution responded so perfectly that even a "Washerwoman at her Tub" will show the grand action of a Medea. The drawing of this subject is reproduced in Souvenirs de Barbizon, a pamphlet in which M. Piédragel has recorded a visit paid to Millet in 1864. His circumstances were then less evil, after struggles as severe as those endured in Paris. A contract by which he bound himself in 1860 to give up all his work for three years had placed him in possession of 1000 francs a month. His fame extended, and at the exhibition of 1867 he received a medal of the first class, and the ribbon of the Legion of Honour, but he was at the same moment deeply shaken by the death of his faithful friend Rousseau. Though he rallied for a time he never completely recovered his health, and on the 20th of January 1875 he died. He was buried by his friend's side in the churchyard of Chalily. His pictures, like those of the rest of the Barbizon school, have since greatly increased in value.

See the article Barbizon; also A. Sensier, Vie et œuvre de J. F. Millet (1874); Piédragel, Souvenirs de Barbizon, &c. (1876); D. C. Thomson, The Barbizon School (1891); Richard Muther, J. F. Millet (1895); Gensel, Millet and Rousseau (1902). (E. F. S. D.)

**Millet** (Fr. millet; Ital. miglietto, diminutive of miglio = Lat. mille, a thousand, in allusion to its fertility), a name applied with little definiteness to a considerable number of often very variable species of cereals, belonging to distinct genera and even subfamilies of Graminaceae. Common millet is *Panicum miliaceum* (German Hirse); it is probably a native of Egypt and Arabia, but has been cultivated in Egypt, Asia and southern Europe from prehistoric times. It is annual, requires rich but friable soil, grows to about 3 or 4 ft. high, and is characterized by its bristly, much branched nodding panicles. One variety has black grains. It is cultivated in India, southern Europe, and northern Africa, and ripens as far north as southern Germany, in fact, wherever the climate admits of the production of wine. The grain, which is very nutritious, is used in the form of groats, and makes excellent bread when mixed with wheaten flour. It is also largely used for feeding poultry, for which purpose mainly it is imported. Hungarian grass, *Setaria italica* (also called *Panicum italicum*), a native of eastern Asia is one of the most wholesome and palatable Indian cereals. It is an annual, grows 4 to 5 ft. high, and requires dry, light soil. German Millet (Ger. Kolbenhirse, Mohar) is probably merely a less valuable and dwarf variety of *S. italica*, having an erect, compact, and shorter spike. The grains of both are very small, only one half as long as those of common millet, but are exceedingly prolific. Many stalks arise from a single root, and a single spike often yields 2 oz. of grain, the total yield being five times that of wheat. They are imported for poultry feeding like the former species and for cage-birds, but are extensively used in soups, &c., on the Continent.

Numerous other species belonging to the vast genus *Panicum*—the largest among grasses, of which the following are among the most important—are also cultivated in tropical and subtropical countries for their grain or as fodder.
grasses, or both, each variety of soil, from swamp to desert, having its characteristic forms.

Polish millet is *P. sanguinale*; *P. frumentaceum*, shamoal, a Deccan grass, is probably a native of tropical Africa; *P. decem-positum* is the Australian millet, its grains being made into cakes by the aborigines. *P. maximum* is the Guinean grass, native of tropical Africa; it is perennial, grows 8 ft. high, and yields abundance of highly nutritious grain. *P. spectabile* is the crop of Angolas. It has been acclimatized in Brazil and other tropical countries. Other gigatic species 6 or 7 ft, high form the field-crops on the banks of the Amazon. Of species belonging to allied genera, *Pennisetum typhoides*, bajree, sometimes also called Egyptian millet or pearl millet, is largely cultivated in tropics, Asia, Nubia and Egypt. Species of *Paspalum*, *Eleusine* and *Milium*, are also cultivated as millets. For Indian millet, see DURGA.

MILLIGAN—MILLIPEDE

MILLIGAN, WILLIAM (1821–1892), Scottish theologian, was born on the 15th of March 1821, the eldest son of the Rev. George Milligan and his wife Janet Fraser. He was educated at the High School, Edinburgh, and, from the age of fourteen, at the university of St Andrews, where he graduated in 1839. In 1843 at the disruption he took the side of those who remained in the Establishment, and in 1844 became minister of Cameron in Fife shire. In 1845, his health having given way, he went to Germany, and studied at the university of Halle. After his return to Scotland and his resumption of his clerical duties he was variously connected in various ways with the church and in various reviews. This led to his appointment in 1860 to the professorship of Biblical criticism in the university of Aberdeen. In 1870 he was appointed one of the committee for the revision of the translation of the New Testament. His fervent piety, and his wide interest in educational and social questions, extended his influence far beyond the circle of theologians. His contributions to periodical literature for many years were numerous and valuable; but his reputation chiefly rests on his works on the *Resurrection* (1890) and *Ascension of our Lord* (1892), his Baird lectures (1886) on the *Revelation of St John*, and his *Discussions* (1893) on that book. All these volumes are distinguished by great learning and acuteness, as well as by breadth and originality of view. He died on the 11th of December 1892.

MILLINER, originally a dealer in goods from the city of Milan in Italy, whence the name. Such goods were chiefly steel work, including cutlery, needles, also arms and armour and the fabrics, ribbons, gloves, and "Milan boxers." The "milling" of London, through which it formed into a Livery Company seems to have been associated with the "Cappers and Hurers," which latter were amalgamated with the "Haberdashers" (q.v.). Minshaw's derivation of the word from milie, thousand ("as having a thousand small wares to sell"), though a typical instance of guessing etymologies, shows the miscellaneous character of their trade in the 16th and 17th centuries. The modern use of the word is confined chiefly to one who makes and sells bonnets and hats for women; but articles of "millinery" include ribbons, laces, &c., usually retailed by haberdashers.

MILLIPED, the popular name of the best known members of a group of the Arthropoda, scientifically known as Diplopoda, and formerly united with the Chilopoda (see CENTIPEDE), the Pauropoda and the Symphyla as an order of the class Myriapoda. This classification, however, has of late years been abandoned on account of the recognition of closer affinity between the Chilopoda (centipeds) and the Hexapoda (insects) than between the Chilopoda and Diplopoda. By modern writers the above-mentioned orders are grouped in the class Diplopoda, which is regarded as an independent class of the phylum Arthropoda, or associated in two superfamilies, the Opisthognata or Opisthognoeata for the Chilopoda and Hexapoda; and the Prosogone or Prosogonoeata for the Diplopoda, Pauropoda and Symphyla. The structural character upon which these superfamilies are based is in the position of the cephalic apertures which open anteriorly in the Prosogonea and posteriorly in the Opisthognoea. Although the Pauropoda and Symphyla are not, strictly speaking, Diplopoda, these three groups of prosogonoeate arthropods are here for convenience considered together.

**CLASS DIPLPODOA.**

**Structure.**—The anterior extremity is provided with a distinct head which by its general form and the nature of its appendages is as sharply marked off from the body as is the case in the Hexapoda. It always bears at least three pairs of appendages, the eyes being present and the Oniscomorpha a peculiar sense organ. The inferior edge of the head plate overhangs the mouth and is termed the labrum. The head of a typical somite consists of the following elements: a dorsal plate, a ventral plate, and a pleural plate, of which each side. To the external margin of the ventral plate or sternum is articulated a pair of legs and between these the leg and the pleural plate is situated the spiracle of the tracheal system. But the tracheation of the Diplopoda presents two peculiarities. The first is the fact that, with the exception of a few of the leg-bearing segments and perhaps one or two of those at the posterior end of the body, a single double-footed or double-footed pair of appendages is articulated on the segments. Hence the segments appear to be double and to be furnished with twice as many legs as is normal in the Arthropoda—a peculiarity which has suggested the term "Diplopoda" or "double-footed" for this group. It is generally believed that each tergal plate results from the coalescence of the terga of two originally distinct adjoining segments; but the same effect would be produced by the enlargement of one of a pair of terga and the complete excavation of the other. It is in favour of the latter view that there is only a single pair, and not two pairs, of stink-glands on each so-called double tergal plate. Unfortunately the history of the development of the segments does not clear up the difficulty since the terga of the double segments are formed independently. In the latter case the terga on each side are bent downwards and inwards towards the mid ventral line; the sternum at the same time is so much reduced that the basal segments of the legs of opposite sides are almost in contact. The pleural plate on each side usually disappears either by suppression or by fusion with the tergum. The sterna with their attached legs often remain free. But quite commonly the coalescence of the skeletal elements is carried to such an extreme that each segment is a solid ring, and two pairs of movable appendages. The last segment is differently constructed from the others. It is always limbless, and usually consists of a complete tergal ring, a single sternal plate, and a pair of movable anal valves which are segmentally closed, but are capable of being opened for the passage of faeces. These anal valves are possibly the homologues of the plural scutes of a normal segment. The appendages are modified
as a single pair of antennae, two or three pairs of jaws and a variable number of walking-legs, of which one or more pairs may be transformed into gonopods. The antennae are short and very similar to the legs. They are preoral in position, and usually consist of seven segments, three or five or more, the distal segment being small as a rule, and furnished with a sense organ which is probably olfactory or tactile in function. The mandibles or jaws of the first pair are the most anterior of the postcranial appendages. They are large, powerful, and usually consist of three or two segments, a basal or

cardio, which is sometimes absent, a second or stipes, and a third or mala, the latter being supplied with a strong tooth and pectinate lamellae. In all Diplopoda, with the exception of Oniscomorpha, there are only two pairs of jaws, those of the second pair forming a large plate, the gnathochilarium, which acts as a lower lip. It consists of several distinct sclerites, two external on each side, the proximal known as the cardo, the distal as the suture, the latter being tipped with one or two lobes (malae) and far exceeding the cardio in size. Between the external plates there is a median proximal plate (mentum) generally of large size and often itself subdivided, and a pair of distal plates (linguae). Behind the base of the gnathochilarium there is a single large transverse plate, the hypostoma. In the Psalaphognathia, the jaws representing the gnathochilarium are differently constructed and an additional pair, the maxillulae, has been recently detected between the gnathochilarium and the mandibles. Behind the gnathochilarium, which from embryological data appears to result from the modification of a single pair of appendages, a legless somite has been detected in some embryos. Possibly the plate referred to above as the hypostoma is its stregmental element.

The heart is a median dorsal vessel composed of a series of chambers each giving off a pair of arteries and furnished with a pair of orifices or ostia. According to Newpoort, the anterior chamber lying in the second segment is prolonged into an aortic trunk from which arise three pairs of lateral arteries dipping down on each side of the alimentary canal and uniting beneath it in a common ventral vessel. The heart is enveloped in a delicate pericardial membrane and is supplied by a pair of lateral alary muscles. The alimentary canal is a single tube extending usually straight through the body from mouth to anus. Only in the Oniscomorpha is it looped, thus suggesting the origin of this short-bodied group of millipedes from long-legged ancestors. A pair of so-called salivary glands opens into the fore-gut near its anterior extremity and one or two pairs of malpighian tubes communicate with the hind-gut at its junction with the broad mesenteric portion of the canal. Respiratory is effected by means of tracheal tubes which communicate with the exterior by means of spiracles situated just above the bases of the walking limbs. Each spiracle leads into a longer or shorter pouch whence the trachea, which are of two kinds, arise. In the majority of the orders the trachea are tufted, that is to say, they form two bundles of short simple tubes springing from the innermost corners of each pouch. In the Oniscomorpha, however, each pouch gives rise to a number of long tubules which extend through the body and supply the segments of the Chilopoda except that they neither branch nor are extensive. As in the Chilopoda and Hexapoda the tracheae are strengthened and kept expanded by a slender spiral filament.

The ventral nerve cord consists of two strands so closely approximated as to be practically fused, with a small gongiophonic enlargement for each pair of legs. Hence in the double segments there are two such ganglia, which in addition to the cranial nerve give off on each side a large branching nerve to other organs in the segment. In the Onisphosphomorpha (Julus, Spirostreptus) and the Oniscomorpha (Gommor, Sphaerotherium) the ganglia are spaced at equal distances on the cord, but in the Merochaeta (Polydesmus) they are grouped in pairs to correspond to the spacing of the legs. The apodous penultimate and anal segments are innervated from the last ganglion of the cord, as are also the gonopods of the males of
**MILLIPEDE**

Diplopods with the soft integument strengthened by weakly chitinized sclerites and furnished above and on the head with transverse rows of short, stout, somewhat squamiform bristles; laterally, on each side of the principal segments, with a thick tuft of long bristles and with a large, silky, white tuft projecting backwards from the posterior extreme. Mandibles one-jointed. Behind them a pair of small, one-jointed maxillae, attached to a median membranous "lingua." Behind the "lingua" and maxillae, a large, double, transverse plate with a long, external sclerite bearing dactyly in Polyxenus an inner short-lobe process and an outer long spiny palpiform branch. The latter, however, is absent in Lophopeltus. These scelerites probably represent the gnathochilarium of the Chilognatha, but the homology between the skeletal elements of the jaws in question is not clearly understood. It has been suggested that they represent two pairs of jaws, but embryological proof of this does not exist.

**Subclass PSEUPLAGNATHA.**

**Order: Penicillata (Polyxenus).**

The head large, usually with lateral eyes. Antennae eight-jointed, attached near the middle of the front of the head. On the dorsal side of the body there are eleven segments, simple and compound. The first four of these bear one pair of legs each, the succeeding four two pairs of legs, the ninth segment only one pair of legs, and the tenth and eleventh or anal segment are legless. There is a narrow sternum area separating the bases of the legs of the two sides. There are no repugnatorial glands on the legs of both sexes, but the legs are modified as gonopods, but the male organ is furnished with a conical penis, which during copulation, it is injected into the genital orifice of the female, which occupies a corresponding position in that sex. The young when first hatched are only three segments in length. In the more advanced species of the subclass, the millipedes of this order are all of small size, measuring at most only a few millimetres in length. The best-known genera are Polyxenus and Lophopeltus, both of which occur in Europe. Other forms have been discovered in the West Indies, North and South America, and Ceylon; and it is probable that the genus has an almost cosmopolitan range. They live under stones or the loosened bark of trees. The carboniferous fossil, Palaeocaepa, is usually referred to this subclass.

**Subclass CHILIONATHA.**

Diplopods with firmly chitinized exoskeleton, sometimes thickly, sometimes sparsely covered with short, simple hairs, but never decorated with tufts or rows of peculiarly modified bristles.
Mandibles, two- or three-jointed; maxillae absent, the jaws of the second pair being represented by the gnathochilarium described above.

Order Oniscomorpha.

Body short and broad, hemispherical in transverse section; convex above, flat below, and capable of being spherically coiled. The exoskeleton of the typical compound segment consists of a vaulted tergum, a pair of free pleuralscleres, two pairs of small tracheal sclerites and two pairs of legs, the latter attached to the ventral membrane, which has no sternal plates. The terginal plates are twelve or thirteen in number, whereas the first is very small, the second enormously expanded laterally, and the last, also enlarged and probably representing at least three segments, extends laterally and posteriorly like a hood over the posterior end of the body without forming a chitinous ring round the anal valves and sternum. In the male the legs of the penultimate pair are sometimes modified as claspers; those of the last pair are always enlarged and prehensile, and bear on their coalesced basal segments a pair of spermatophore-mounting processes analogous to the phallopods of other groups. Apart from these organs the male has no penis, the seminal ducts perforating the coxae of the legs of the second pair. This order contains two well-marked suborders, the Glomeridae and the Zaphronioidae. The Glomeridae, comprising the families Glomeridae, Gerasitidae, Onomeridae, have the antennae approximated on the head, the eyes unicellular and twelve (rarely eleven) tergal plates. To this group belong the common pill-millipedes of Europe and North Africa. In North America the Onomeridae alone are found. The Zaphronioidae, with the single family Zaphroniidae, have the antennae at the sides of the head, the eyes composed of a spherical cluster of ocelli, and always thirteen tergal plates. This group is common in the tropical and southern continents of the Old World, having representative genera in South Africa, Madagascar, India, Malaysia, Australia and New Zealand. They are much larger forms than the Glomeridae, large specimens reaching two or three inches in length. In addition to the characters mentioned above the Oniscomorpha differ from all other Diplopoda in having long tubular tracheae and the alimentary canal bent upon itself.

Order Limacormorpha.

Resembling the Oniscomorpha in the shape and structure of a typical segment, except that the tracheal plates are unrepresented; in the facts that the last tergal plate does not form a complete ring round the anal area, and that the last pair of legs in the male are modified; but differing from them in that the body consists of nineteen or twenty segments, is elongate, and tapers anteriorly and posteriorly, the second and last tergal plates being small; in the presence of the male of a pair of long hairy protrusible pens between the legs of the second and third pairs, and in the structure of the genopods, which, instead of being chelate, terminate in a slender, tapering tarsal segment. This order contains two families: Zaphroniidae (Zaphroniinae) and Glomeridae (Glomeridesmidae), the former from tropical Asia, the latter from tropical America. The largest of these millipedes reach a length of only about 7 mm. Nothing special is known of their habits.

Order Colobognatha.

Body elongate, capable of being spirally coiled, consisting of a large and indefinite number of segments, each being furnished with a distinct often large sternal area, and with the pleuralsclerite or membrane distinct from the tergum. The last tergal plate forms a complete ring round the anal valves. Legs with coxal pouches; those of the seventh segment transformed into genopods of a very simple type in the male, which is also furnished with a double penis completely or partially confluent with the coxae of the legs of the second pair. Head and second pair of legs are triangulir or piriform, in the latter case the gnathes reduced in size and complexity. Repugnatorial pores present and lateral. The genera of this order are divisible into three families: the Platypodidae (Platypus, Pseudesmus), Polydesmidae (Polydesmus, Stiphonotus), Siphono-phoridae (Siphonophora). Of these the Siphono-phoridae have departed least and the Siphonophoridae most from the typical Diplopod in the structure of the mouth parts. The group is for the most part tropical, one genus only, Polydesmus, extending as far north as Central Europe.

Order Ascospermophorpha.

Body elongate, consisting of from twenty-six to thirty-two segments, but not varying within specific limits; the pleurals coalesced with the terga, the sterna free. More or fewer of the anterior ten pairs of legs may be modified in the males, but no true phallopods are differentiated, the function of seminal receptacles being performed (according to C. Verhoeff) by the essectile coxal pouches of the two pairs of legs of the eighth segment. The seminal ducts in the male perforate the coxae of the legs of the second pair. There are no repugnatorial pores, and the terga are furnished with the marginal limits of symmetrically placed hairs or bristles. On the posterior border of the last tergal plate there is a pair of spinning papillae. The millipedes of this order, also called Coelochaeta, are referable to several families: Chordeumidae (Chordemma), Craspedosomidae (Craspedosoma), Heterorchordusidae (Heterorch- desmus), &c. The Heterorchordusidae belong to the Oriental region, extending from India to New Zealand. The others are particularly abundant in genera and species in North and Central America and Europe; but are unknown in Africa, south of the Sahara.

Order Proterogomphorpha.

Differing from the Ascospermophorpha in that the number of segments is large and variable; they are furnished with repugnatorial pores, and not with the three pairs of setae. In the males the anterior appendages of the seventh segment are modified as phallopods, and the seminal ducts perforate the coxae of the legs of the second pair.

This order, containing the family Lysiopetalidae (Lysiopetalum), is widely distributed in Europe and North America. Large examples of some of the species, e.g. L. xanthinum, reach a length of 4 or 5 ins.

Order Merocentata.

Resembling the Proterogomphorpha in having only the anterior appendages of the seventh segment converted into phallopods and the seminal ducts perforating the coxae of the second legs in the males; but differing essentially in that the sterna are
MILLIPEDE

solidly welded to the rest of the exoskeleton of the segments, which are either nineteen or twenty in number, in the absence of eyes and of spinning papillae, and in having six-jointed legs. This order is cosmopolitan in distribution and consists of a very large number of genera which are especially referred to the single family Polydesmidae; by others to numerous families. Many species are brightly coloured, and some individuals of the Oriental genus

c. Head.

da. Antenna.

t. Tergal plate of first body segment.

g. Ditto of seventh.

Platybranchus may reach a length of 5 ins. The segments are provided with lateral laminate or tubercular expansions bearing the repugnatorial pores, which are only very rarely absent.

Order *Opisthospermoidea*.

Resembling the Proterospermoidea in possessing a large and variable number of segments, each of which, with the exception of the last and the anterior, which are four in number, is furnished with paired appendages, differing essentially from them in that the posterior pair of appendages of the seventh segment are converted into phallopods, and the anterior into protective coeleopods in the male, and that the seminal ducts of this sex in each of the segments eke out the second pair but are usually associated with a distinct penis situated immediately behind them. The genera of this order present greater diversity of structure than is found in the other orders and are referred to the following families: the Stemmiuloidea (Monochaeta); the Spiroboloidea (Anochaeta); the Spirostreptidea (Diplochaeta); and the Juloidea (Zygochaeta).

In the Stemmiuloidea the sterna are fused with the pleurae partially or wholly, and the terminal end is bisegmented; there are two pairs of spinning papillae on the last tergite; the penis is a single long tube, and the eyes are represented by one or two large lenses on each side of the head. The genus Stemmiulus, constituting the Stemmiuloidea, is represented in the Oriental, Ethiopian, and Neotropical regions. The possession of silk-glands this suborder resembles the Ascospermoidea and Proterospermoidea, and should perhaps be ranked as an order apart from the Opisthospermoidea.

The Spiroboloidea, containing one family, the *Spiroboloidea* (Spirobolus, Rhinoecius, &c.), have the sterna and pleurae coalesced, the tarsi undivided; no spinning papillae, no penis, the eyes represented by a group of ocelli, which is the characteristic feature of this family. The species of the family are often very large, and it is to be noted that the family is represented in the tropics of Africa and Asia.

In the Spirostreptidea the segments are divisible by a transverse line both in the tropics, where the species and genera are numerous and specimens of large size, i.e. 6 ins. or over, are met with.

The Juloidea resemble the Spiroboloidea in many particulars, but the fourth segment is foetal, and the fifth has two pairs of limbs; the male has a distinct and double penis, and in both sexes the stipes of the mandibles are prolonged to the proximal end of the segment which is relatively small. The distribution of this order, which contains several families: *Spirostreptus* (Spirostreptus, Rhynchoecius, Camboldia, Cambola, Fulmorna, &c.), is practically the same as that of the family Spiroboloidea. Species over 1 in. in length are met with in the tropics of Africa and Asia.

The Juloidea differ from the Spirostreptidea in having the third segment limbless, the first, second and fourth with a single pair of appendages, and the stipes of the gnathochilarium not united; but are otherwise in the main line behind the very small prothorax.

The best marked family of this group is the *Julidae*, which is widely distributed in the northern hemisphere. Its species and genera (*Julus, Pteronrurus*) are abundant in Europe. Another European family, the *Nemaseidae*, is founded for the genus *Nemasema*, which is remarkable for having the sterna free.

Habits, &c.—Millipedes are principally cryptozoic, living under stones or logs of wood in damp, secluded localities. They feed almost wholly upon decaying vegetable matter, and drink a considerable quantity of water. Some of the tropical species emerge in numbers from their hiding-places after heavy rains, and crawl out on the surface of the ground to imbibe the moisture in broad daylight. Their method of progression over level ground is quite peculiar. The body is held in a straight line and is propelled by a succession of wave-like movements of the legs, which are moved at the same time, each opposite group rising and falling. Some forms, e.g. *Stemmiulus*, have been described as attempting to evade capture by a hopping action caused by vigorous jerking and wriggling of the body. Many of the species are very voracious feeders on the decomposing vegetable matter, and with the existence of the nauseous secretion of the repugnatorial galls suggests that the coloration is aposematic or of warning significance.

The formation between the sexes takes place before oviposition. In the Opisthospermoidea the males and females coil together with the ventral surface of the anterior ends of their bodies opposed, the male holding the female securely by the head while the extended phallopods carry the asexual organs of the female. In the Polydesmidae pairing is effected in the same way except that the male and female instead of interlocking remain extended, the male clasping the female with his legs. In the Oniscoidei the sexes also pair front to front, not head to head, however, but with the anal segment of the male can be applied to the second pair of postoral appendages in the female. Some males of this group, e.g. *Spiroceuthorium*, have a stridulating organ on their posterior gonopods and stridulate when facing the females.

The method of disposing of the young, which usually have only three pairs of legs at hatching, differs in various groups. In *Julus* and Polydesmidae the female burrows below the surface of the moist earth and males and females remain together, but in other Haplopoda, e.g. the South American species, *Acraspius procerus*, that lived in the London Zoological Gardens, buried herself, coiled her eggs, and then left them to the care of nature, the female being present when the young were hatched again. Millipedes, like the Stemmiuloidea and Ascospermoidea, which possess silk-glands, spin silk cases, cases for the protection of their eggs. Immature specimens of these groups spin similar silk cases at the time of hatching, and these cases are used as dew-sheds and nests, which are provided with organs of moulting by the same means. Immature cases are formed of some species of Polydesmidae, e.g. by the tropical African *Oxydesmus*, which is given to the care of nature. However, the animal makes use of its own voided excrement in the formation of these receptacles.

A considerable number of Chilognatha of doubtful systematic position have been recorded in the family of the carboniferous formation. The best known are *Acanthuspteryx* and *Ethaphorium*. Species referred to existing genera have been discovered in amber beds of Oligocene age.

**CLASS PAUPOPODA.**

As in the Diplopoda there is a distinct head bearing a pair of antennae and two pairs of jaws. On each side of the head there is a distinct eye, which is very rarely degenerate, although the external cuticle shows no corneal thickening nor the epidermis retinular specialization, and optic nerves are absent from the brain. The antennae are structurally unique in the Arthropoda. They are furnished with four short basal segments from the distal of which arise two one-jointed branches, an external thinner and an internal thicker. The external or postaxial branch is tipped with a single long annulate flagelliform bristle with a rounded apical knob; and this is usually protected by a pair of pre- and postornamental plates and a globular, usually pedunculated, sense organ between them. The mandibles of the jaws are some large and one-jointed. Those of the second pair are very short, piriform, and attached to the mouth by a long basal segment and a very short pair of appendages. In all cases these two pairs of jaws are the skeleton forming a kind of lower lip to the mouth. The correspondence between these mouth parts and those of the Diplopoda is not understood. No doubt the mandibles are homologous to the two; but whether the mandibles as understood are homologous in the Pauropoda is not understood. No doubt the mandibles are homologous in the Pauropoda is not understood. No doubt the mandibles are homologous in the Pauropoda is not understood. No doubt the mandibles are homologous in the Pauropoda is not understood. No doubt the mandibles are homologous in the Pauropoda is not understood. No doubt the mandibles are homologous in the Pauropoda is not understood.
are questions to which no answer can as yet be given. Judging from the segmentation and the appendages the body is composed of twelve somites, including the last or anal, which, like the penultimate somite, is limbless. Each somite in front of the penultimate

bears a single pair of legs, nine pairs of which are fully developed ambulatory limbs, while those of the first segment are reduced to

After Lubbock.

**FIG. 13.—Enlarged view of Pauropus huskleyi, from ventral side.** A pair of bud-like processes. The first and last pairs of ambulatory limbs consist of five segments; in the remaining pairs the terminal segment may be subdivided into two, so that there may be six segments in all. The ambulatory limbs are usually terminated by three claws, a principal and two subsidiary, each claw being accompanied by a membranous pad. Between these limbs, which are relatively longer and stronger than in the Diplopoda and evenly spaced on each side of the body, extends a soft-skinned sternal area. The distensible pleural region of the body is also membranous, but the dorsal area is covered by chitinous plates or terga, usually six in number, excluding that of the anal segment; each of the anterior five of these overlies two limb-bearing somites, the first covering the somite of the rudimentary limbs and of the first pair of locomotor legs, the second those of the second and third pairs of locomotor legs, and so on. This condition is an adumbration of the far completer fusion of somites seen in the Diplopoda. The sixth tergal plate belongs to the limbless penultimate somite.

The duplet character of the first five terga is suggested in *Pauropus* by the presence of two rows of sensory bristles; there being only one such row upon the sixth tergum. In the aberrant genus *Brachypauropus* the evidence is practically completed by the correspondence in number between the terga and pairs of legs, there being a divisional line between the two rows of setae. On each side of the body there are two long pubescent tactile setae situated on the second to the sixth terga in *Pauropus*, and on the pleural area corresponding to these terga in *Brachypauropus*.

The cerebral mass of the nervous system is large and when viewed from above is seen to consist of two lobes defined by a median groove. In the absence of eyes no optic nerves are given off. Beneath these are two antennal lobes whence arise, close together, the antennal nerves. Two short commissural cords connect the cerebral mass with the suboesophageal ganglion, a composite mass formed of the nervous centres which supply the two pairs of jaws and the rudimentary legs of the first pair. Behind this large ganglion the cord, which shows superficially no trace of its double origin, presents a ganglionic swelling for each pair of legs. No circulatory or respiratory organs have been detected.

The alimentary canal consists of a short, narrow fore-gut, a large, straight mid-gut, and a moderately long hind-gut which is itself composed of two parts, an anterior narrow tube which opens into

are never more than four-jointed; they are always smaller than the others, and are sometimes reduced to mere bud-like processes. They belong to the first segment behind the head. The segment represented by the last tergal plate has no anal limits; but articulated to its posterior is a pair of large, backward-directed sclerites, which are perforated by the ducts of two spinning glands. These segments are regarded by some authors as the appendages of the last abdominal terga.

FIG. 15

and hind-guts. The generative organs in the female are very simple, and much like those of the Diplopoda. In the male they are highly complex, and unlike those of any known Arthropod in certain particulars. The wide, unpaired ovary extends nearly to the posterior end of the body. Anteriorly it passes into an oviduct which is unpaired throughout its length, and opening by a pair of small lateral paired spermatophore glands. In the male the anterior, an abruptly narrowed tube, curves round the nerve-cord and opens by a single sub-median orifice in the third segment. Just within the orifice there opens into the oviduct the short duct of a spherical mass, the spermatophore. In the male this is the only trace of a female ovary. Sometimes it is single, sometimes divided into an anterior and a posterior mass, and sometimes merely constricted. It lies above the intestine in the posterior half of the body in the adult, but at least in the larval stages in some cases one or both of them have been detected, its position is more lateral. Leading from the sperm masses there may be as many as three slender short ducts which soon expand into wider tubes. These tubes, regarded as seminal vesicles, after forming a complex of loops, coiled and coiled prolongations, ultimately unite beneath the intestine in a single tube which passing forwards divides on each side of the alimentary canal to terminate in the two pairs situated just behind the bases of the second pair of complete legs, and in the region of the penis there is an accessory gland on the duct, and a little farther back a much larger glandular swelling.

The Pauropods are divided into three rather sharply defined groups or families which may be reduced and characterized as follows: Pauropus is a group first defined by the first tergal plate. Anal segment not covered by the sixth tergal plate. Terga of the first ten body segments fused in couples. Tactile setae situated on the lateral portions of the terga which are neither sculptured nor spinous.

Brachypauropodidae. — Head and anal segment free and the smoothest of all; but each of the double terga of the Pauropodidae divided into an anterior and posterior plate by a transverse band of muscles. The anterior terga of each pair of plates is articulated by a longitudinal intumescence strip. The tactile setae arising from the pleural area of the segments (Brachypaus.)

Eurypauropodidae. — Body wide and oniciform, the head and the anal segment concealed and flattened; and pedunculate terga respectively fused in the Pauropodidae, but thickly sculptured or spinous. The tactile setae situated beyond the edge of the terga, as in the Brachypauropodidae. (Eurypauropus.)

The genus Pauropus is probably world-wide in distribution, since it has been found in South America, Brazil, and in Sicily. The two known species of Brachypaus were found respectively in Italy and Austria. Eurypauropus has representatives in North America and Europe. Examples of Pauropus are extremely agile animals and useful in the study of them in their movements; those of Eurypauropus, on the contrary, are extremely slow and quite comparable in lack of agility to the common pill-millipe. They are universally found in woods, under stones, fallen branches, dead leaves or other damp situations. They are exceedingly nouritous. The young upon hatching has four segments and three pairs of legs representing the first three pairs of ambulatory legs of the adult. The last two segments are appendages, the first being the first pair of legs, and the second the second; the third pair of legs further arises through four successive moult, and gradually acquires its full complement of segments and limbs.

CLASS SYMPHyla

Prosogonete Arthropods, differing in many important particulars from the Diplopoda and Pauropoda. The axis of the head lies in the same straight line as that of the body of the three segments and not as a single tube as in Diplopoda and Pauropoda. There are no eyes. The antennae are very long and many-jointed. Four pairs of gnathites attached to the underright of the head have been detected. The first pair (mandibles) are two-jointed, as in many Diplopoda. The second pair (labium) are minute, one-jointed and articulated to a median lobe or hypopharynx which is supported by two chitinous skeletal rods. The third pair (maxillae) consist of a long, basal segment terminating distally in two lobes; near the distal segments there is an evident minute one of two-jointed process, regarded as a palpus. Between the maxillae lies a large, double plate (labium or maxillae of second pair) which is attached proximally to two rod-like basal segments and terminates distally in two pairs of very short legs. The maxillae and maxillae of second pair are often side fifteen tergal plates. The first of these, immediately succeeding the head, is very short; the remainder are large and sub-equal in size. The adult animal is furnished with twelve pairs of walking legs, which, with the second pair of mandibles, are long and terminal with two powerful claws. The proximal segment bears internally a slender, cylindrical process which may be termed the parapod. It has been asserted that the segment bearing this parapod is in reality the second and that the true basal segment or coxa is embedded in the ventral integument. The legs of the first and second pairs never have the parapod, but are invariably present in the remaining ten pairs. The legs of the first pair

FIG. 16.—1, Scutigrella spl highly magnified (slightly reduced and reversed); b, b, bones of first pair; c, antennae. 2. One of the functional antennae enlarged (from Wood Mason), showing the five joints and terminal pair of claws; b, parapod.
angles produced and angular, whereas in Scutigera they are rounded. Both genera are widely distributed and arc represented, in Europe, South America, Siam, &c. Large specimens reach a limit of between six and seven millimetres. They live in earth, beneath stones, dead leaves or fallen branches, and resemble diminutive centipedes (Scolopendra or Lithobius) both in appearance and movements. The Symphysa have frequently been compared with the Thyasurus Hexapods, the parasites with their adjacent coccyleous vesicles in Scolopendra and similar to the coccyleous vesicles of such an insect as Machilis; while the posterior spinning sclerites or cerci of the former bear much resemblance to the cercopods of Japyx. It must be remembered, however, that the spinning glands or coccyleous organs occur in some other orders of insects. The Symphyse and open tube papilliform processes of the last tergal plate, which are certainly not appendages, however, if the papillae are the homologues of the cerci in Scolopendrella, these cerci cannot be morphologically comparable to the cercopods of Japyx or other insects. There is no indication that the spines of the Symphysa are comparable with the cerci, even if the full force of the arguments in favour of relationship between the Symphyse and the Hexapoda be admitted, the Symphyse, nevertheless, differ essentially from the Hexapoda in the anterior position of the generative orifice, and in the presence of twelve pairs of similar ambulatory limbs. (R. T. P.)

MILLOM, a market town in the Egremont parliamentary division of Cumberland, England, in the extreme south-west of the county, on the Furness railway. Pop. of urban district (1901), 3,112. The town of Miller Early in date, is chiefly of interest for its curious pillars, alternately round and octagonal, and for a window in the north aisle, which has five lights, and is known, on account of its unique shape, as the "fish-window." A massive roadstead stands in the churchyard. Millom Castle, dating from shortly after the Conquest, was fortified in the 14th century by Sir John Huddleston, whose descendants held it until 1774. For centuries, they exercised the power of life and death; a stone stands where the gallows were formerly erected, and indicates that here they exercised jura regalia. Though strongly built, the castle was never of great size, and it has been largely dismantled. A fine carved staircase, however, still exists in the main chapel. In 1648 the Parliamentary forces besieged Millom Castle, and early in the 19th century its park was converted into farmland. In the neighbourhood of Millom there are vast furnaces and high moulding and long afterwards as the leading authority in Congress. As chairman of the Ways and Means Committee of the House of Representatives in 1887-1889, during President Cleveland's first administration, he led the fight for reform.
MILMAN—MILNER, VISCOUNT

MILMAN, HENRY HART (1701–1868), English historian and ecclesiastic, third son of Sir Francis Milman, Bart., physician to George III., was born in London on the 10th of November 1701. Educated at Eton and at Brasenose College, Oxford, his university career was brilliant. He gained the Newdigate prize with a poem on the *Apollo Belvedere* in 1812, was elected a fellow of Brasenose in 1814, and in 1816 won the English essay prize with his *Comparative Estimate of Sculpture and Painting*. In 1816 he was ordained, and two years later was presented to the living of St Mary’s, Reading. Milman had already made his appearance as a dramatic writer with his tragedy *Fazio* (produced on the stage under the title of *The Italian Wife*). He also wrote *Samar, the Lord of the Bright City*, the subject of which was taken from British legend, the “bright city” being Gloucester; but he failed to invest it with serious interest. In subsequent poetical works he was more successful, notably the *Fall of Jerusalem* (1820) and the *Martyr of Antioch* (1822). The influence of Byron is seen in his *Belshazzar* (1822). A tragedy, *Anne Boleyn*, followed in 1826; and Milman also wrote “When our heads are bowed with woe,” and other hymns; an admirable version of the Sanskrit epic of Nala and Damayanti; and translations of the *Agomnon of Aeschylus* and *Scoli* of *The Iliad*. He became professor of poetry at Oxford, and in 1827 he delivered the Bampton lectures on the character and conduct of the apostles as an evidence of Christianity. His poetical works were published in three volumes in 1839.

Turning to another field, Milman published in 1820 his *History of the Jews*, which is memorable as the first by an English clergyman which treated the Jews as an Oriental tribe, recognized sheikhs and amirs in the Old Testament, sifted and classified documentary evidence, and evaded or minimized the miraculous. In consequence, the author was violently attacked and his inevitable prevarication was delayed. In 1835, however, Sir Robert Peel made him rector of St Margaret’s, Westminster, and canon of Westminster, and in 1840 he became dean of St Paul’s. By this time his unpopularity had nearly died away, and generally revered and beloved, he occupied a dignified and enviable position, which he constantly employed for the promotion of culture and in particular for the relaxation of subscription to ecclesiastical formularies. His *History of Christianity to the Abolition of Paganism in the Roman Empire* (1840) had been completed before his untimely death, but was afterwards published by his literary executor and a more complete edition; while the continuation of his work, his great *History of Latin Christianity* (1855), which has passed through many editions. In 1838 he had edited Gibbon’s *Decline and Fall of the Roman Empire*, and in the following year published his *Life of Gibbon*. Milman was also responsible for an edition of Horace, and when he died he had almost finished a history of St Paul’s Cathedral, which was completed and published by his son, A. Milman (London, 1868), who also collected and published in 1879 a volume of his essays and articles. Milman died on the 24th of September 1868, and was buried in St Paul’s Cathedral. By his wife, Mary Ann, a daughter of Lieut.-General William Cockell, he had four sons and two daughters. His nephew, Robert Milman (1816–1876), was bishop of Calcutta from 1867 until his death, and was the author of a *Life of Torquato Tasso* (1850).

MILNE-EDWARDS, HENRY (1800–1885). French zoologist, the son of an Englishman, was born in Bruges on the 15th of October 1800, but spent most of his life in France. At first he turned his attention to medicine, in which he graduated at Paris in 1823; but his passion for natural history soon prevailed, and he gave himself up to the study of the lower forms of animal life. One of his earliest papers (*Recherches anatomiques sur les crustacés*), which was presented to the Academy of Sciences in 1829, formed the theme of an elaborate and eulogistic report by G. Cuvier in the following year. It embodied the results of two dredging expeditions undertaken by him and his friend J. V. Audouin during 1826 and 1828 in the neighbourhood of Granville, and was remarkable for clearly distinguishing the marine fauna of that portion of the French coast into four zones. Much of his original work was published in the *Annales des sciences naturelles*, with the editorship of which he was associated from 1834. Of his books may be mentioned the *Histoire naturelle de crustacés* (3 vols., 1837–1841), which long remained a standard work; *Histoire naturelle des corallifères*, published in 1858–1860, but begun many years before; *Leçons sur la physiologie et l’anatomie comparée de l’homme et des animaux* (1857–1881), in 14 volumes; and a little work on the elements of zoology, originally published in 1834, but subsequently remodelled, which enjoyed an enormous circulation. He was appointed in 1841 professor of entomology at the Muséum d’histoire naturelle, where twenty-one years later he succeeded Geoffroy Saint-Hilaire in the chair of zoology. The Royal Society in 1856 awarded him the Copley medal in recognition of his zoological investigations. He died in Paris on the 29th of July 1885. His son, Alphonse Milne-Edwards (1835–1900), who became professor of ornithology at the museum in 1876, devoted himself especially to fossil birds and deep-sea exploration.

MILNER, ALFRED MILNER, VISCOUNT (1853— ), British statesman, was born at Bonn on the 23rd of March 1854, the only son of Charles Milner, M.D., whose wife was a daughter of Major-General Ready, sometime governor of the Isle of Man. His paternal grandfather, an Englishman, settled in Germany and married a German lady; and their son, Charles Milner, practised as a physician in London and became later Reader in English at Tübingen University. Alfred Milner was educated first at Tübingen, then at King’s College, London, and under Jowett as a scholar of Balliol College, Oxford, from 1872 to 1876. He graduated in 1877, with a first class in classics, having won the Hertford, Craven, Eldon and Derby scholarships, and was elected to a fellowship of New College. At Oxford he formed a close friendship with Arnold Toynbee, and was associated with his schemes of social work; and subsequently he wrote a tribute to his friend, *Arnold Toynbee: a Reminiscence* (1865). In 1881 he was called to the bar at the Inner Temple and joined the staff of the *Pall Mall Gazette* under John Morley, becoming assistant editor under W. T. Stead. In 1885 he abandoned journalism, and became Liberal candidate for the Harrow division of Middlesex at the general election, but was defeated. He was appointed private secretary to Mr Goschen (then Lord Goschen), and in 1889, when Goschen became chancellor of the exchequer, was appointed his principal private secretary. It was by Goschen’s influence that in 1890 he was made under-secretary of finance in Egypt. He remained in Egypt four years, it being period of office coinciding with the first great reforms, after the danger of bankruptcy had been avoided. Milner returned to England in 1892, and was appointed chairman of the Board of Inland Revenue, being made C.B. in 1894 and K.C.B. in 1895. Shortly after his return to England he published his *England in Egypt*, which at once became the authoritative account of the work done since the British occupation.

Sir Alfred Milner remained at the Board of Inland Revenue until 1897. He was regarded as one of the clearest-headed and most judicious officials in the British service, and his position as a man of moderate Liberal views, who had been so closely associated with Goschen at the Treasury, Cromer in Egypt and Hicks-Beach (Lord St Aldwyn) and Sir W. Harcourt while at the Inland Revenue, marked him out as one in whom all parties might have confidence. The moment for testing his capacity (for he was now come) in April Lord Goschen resigned his posts of high commissioner for South Africa and governor of Cape Colony. The situation resulting from the Jameson raid (see TRANSVAAL AND SOUTH AFRICA) was one of the greatest delicacy and difficulty, and Mr Chamberlain, now colonial secretary, selected Milner as Lord Rosmead’s successor. The choice was cordially approved by the leaders of the Liberal party, and warmly recognized at a farewell dinner presided over by Mr Asquith (March 28th, 1897). The
appointment was avowedly made in order that an acceptable British statesman, in whom public confidence was reposed, might go to South Africa to consider all the circumstances, and to formulate a policy which should combine the upholding of British interests with the attempt to deal justly with the Transvaal and Orange Free State governments.

Sir Alfred Milner reached the Cape in May 1897, and after the difficulties with President Kruger over the Aliens’ Law had been patched up he was free by August to make himself personally acquainted with the country and peoples before deciding on the lines of policy to be adopted. Between August 1897 and May 1898 he travelled through Cape Colony, the Bechuanaland Protectorate, Rhodesia and Basutoland. The better to understand the point of view of the Cape Dutch and the burghers of the Transvaal and Orange Free State, Milner also during this period learned both Dutch and the South African “Taal.” He came to the conclusion that there could be no hope of peace and progress in South Africa while there remained the “permanent subjection of British to Dutch in one of the Republics.” He also realized—as was shown by the triumphantly re-elected President Kruger—that the harmony of this country (see TRANSVAAL) gradually became more and more contentious. When war broke out, October 1899, Milner rendered the military authorities “unfailing support and wise counsels,” being, in Lord Roberts’s phrase “one whose courage never faltered.”

In February 1901 he was called upon to undertake the administration of the two Boer states, both now annexed to the British Empire, though the war was still in progress. He thereupon resigned the governorship of Cape Colony, while retaining the post of high commissioner. The work of reconstructing the civil administration in the Transvaal and Orange River Colony could only be carried on to a limited extent while operations continued in the field. Milner therefore returned to England to spend a “hard-begged holiday,” which was, however, mainly occupied in work at the Colonial Office. He reached London on the 24th of May 1901, had an audience with the king on the same day, was made a G.C.B. and privy councillor, and was raised to the peerage with the title of Baron Milner of St James’s and Cape Town. Speaking next day at a luncheon given in his honour, answering critics who alleged that with more time and patience on the part of Great Britain war might have been avoided, he asserted that what they were asked to “conciliate” was “panoplied hatred, insensate ambition, invincible ignorance.” Meanwhile the diplomacy of 1899 and the conduct of the war had caused a great change in the attitude of the Liberal party in England towards Lord Milner, whom Mr Leonard Courtney even characterized as “a lost mind.” A violent agitation for his recall, in which Sir Henry Campbell-Bannerman joined, was organized, but without success, and in August he returned to South Africa, where he plunged into the herculean task of remodelling the administration.

In the negotiations for peace he was associated with Lord Kitchener, and the terms of surrender, signed at Pretoria on the 31st of May 1902, were drafted by him. In recognition of his services he was, on the 15th of July, made a viscount.

Immediately following the conclusion of peace Milner published (June 21) the Letters Patent establishing the system of crown colony government in the Transvaal and Orange River colonies, and exchanging his title of administrator to that of governor. The reconstructive work necessary after the ravages of the war was enormous. He provided a steady revenue by the levying of a tax of 10% on the annual net produce of the gold mines, and devoted special attention to the repatriation of the Boers, land settlement by British colonists, education, justice, the constabulary, and the development of railways. While this work of reconstruction was in progress domestic politics in England were convulsed by the tariff reform movement and Mr Chamberlain’s resignation. Milner, who was then spending a brief holiday in Europe, was urged by Mr Balfour to take the vacant post of secretary of state for the colonies. This offer he declined (Oct. 1, 1903), considering it more important to complete his work in South Africa, where economic depression
was becoming pronounced. He was back in Johannesburg in December 1903, and had to consider the crisis in the gold-mining industry caused by the shortage of native labour. Reluctantly he agreed, with the consent of the home government, to the proposal of the mineowners to import Chinese coolies on a three years' contract, the first batch of Chinese reaching the Rand in June 1904.

In the latter part of 1904 and the early months of 1905 Lord Milner was engaged on the elaboration of a scheme to provide the Transvaal with a system of "representative" government, a half-way house between crown colony administration and that of self-government. Letters patent providing for representative government were issued on the 31st of March 1905. For some time he had suffered in health from the incessant strain of work, and he determined to retire. He left Pretoria on the 2nd of April and sailed for Europe on the following day. Speaking at Johannesburg on the eve of his departure, he recommended to all concerned the promotion of the material prosperity of the country and the treatment of Dutch and British on an absolute equality. Having referred to his share in the war, he added: "What I should prefer to be remembered by is a tremendous effort subsequent to the war not only to repair the ravages of that calamity but to re-start the colonies on a higher plane of civilization than they have ever previously attained." He left South Africa while the economic crisis was still acute and at a time when the voice of the critic was audible everywhere; but, in the words of the colonial secretary (Mr Alfred Yeatman) he had in the eight eventful years of his administration "laid deep and strong the foundation upon which a united South Africa would arise to become one of the great states of the empire." On his return home his university honoured him with the honorary degree of D.C.L.

Experience in South Africa had shown him that underlying the difficulties of the situation there was the wider problem of imperial unity. In his farewell speech at Johannesburg he concluded with a reference to the subject: "When we who call ourselves Imperialists talk of the British Empire we think of a group of states bound, not in an alliance—for alliances can be made and unmade—but in a permanent organic union. Of such a union the dominions of the sovereign as they exist to-day are only the raw material." This thesis he further developed in a magazine article written in view of the colonial conference held in London in 1907. He advocated the creation of a permanent deliberative imperial council, and favoured preferential trade relations between the United Kingdom and the other members of the empire; and in later years he took an active part in advocating the cause of tariff reform and colonial preference.

In March 1906 a motion censuring Lord Milner for an infraction of the Chinese labour ordinance, in not forbidding light corporal punishment of coolies for minor offences in lieu of imprisonment, was moved by a Radical member of the House of Commons. On behalf of the Liberal government an amendment was moved, stating that "This House, while recording its condemnation of the flogging of Chinese coolies in breach of the law, desires, in the interests of peace and conciliation in South Africa, to refrain from passing censure upon individuals." The amendment was carried by 355 votes to 135. As a result of this left-handed censure, a counter-demonstration was organized, led by Sir Bartle Freere, and a public address, signed by over 370,000 persons, was presented to Lord Milner expressing high appreciation of the services rendered by him in Africa to the crown and empire.

**MILNER, JOSEPH (1744-1797).** English evangelical divine, was born at Leeds and educated at Leeds grammar-school and Cambridge. After taking his degree he went to Thorparch, Yorkshire, as curate and assistant schoolmaster. Subsequently he became head master of Hull grammar-school, and in 1768 he was chosen afternoon lecturer at Holy Trinity church, Hull. He became a strong supporter of the evangelical movement of the period, and greatly contributed to its success in Hull. In addition to his work as head master, he took charge of North Ferriby parish, about 9 m. from Hull. His published works include essays and numerous sermons, but his best known work is the History of the Church of Christ (London, 1794-1809). He lived to complete the first three volumes, and two more were added by his brother, Isaac Milner (1750-1820), dean of Carlisle, who re-edited the whole work in 1810.

**MILNGAVIE** (locally pronounced Millguy), a police burgh of Dumbartonshire, Scotland. Pop. (1901), 3481. It lies 6 m. N.N.W. of Glasgow by the North British railway. The chief industries include bleach-fields, dye-works, a distillery and a paper mill; but the town is largely a residential quarter for Glasgow business men. Close to the town are two reservoirs, Muirdock (62 acres) and Craigmaddie (88 acres), in which is stored the water from Loch Katrine. Muirdock Castle, 1 m. N. of Milngavie, is an old stronghold of the Grahams; in Balderock parish, about 2 m. E., stands a cromlech, called "the Auld Wives' Lift" (400 ft. high), commanding a fine view of the lands between the Forth and Clyde. Douglasloch Loch, 3 m. S.E., contains several rare aquatic plants.

Milo, or Milon, of Crotona, Greek athlete, lived about the end of the 6th century B.C. He was six times crowned at the Olympic games and six times at the Pythian for wrestling, and was famous throughout the civilized world for his feats of strength—such as carrying an ox on his shoulders through the stadium at Olympia. In his native city he was much honoured, and he commanded the army which defeated the people of Sybaris in 511. The traditional account of his death is often used to point a moral: he found a tree which some local cult had consecrated and which he undertook to rend asunder; but the wedge fell out, and the tree closed on his hand, imprisoning him till wolves came and devoured him. His name became proverbial for personal strength (Diod. Sic. xii. 9; Pausianis vi. 14; Strabo vi. 263; Herodotus ii. 137).

**MILO, TITUS ANNIUS,** Roman political agitator, was the son of C. Caius Cæsar, but was adopted by his mother's father, T. Annius Luscus. He joined the Pompeian party, and organized bands of mercenaries and gladiators to support the cause by public violence in opposition to P. Clodius, who gave similar support to the democratic cause. Milo was tribune of the plebs in 57 B.C. He took a prominent part in bringing about the recall of Cicero from exile, in spite of the opposition of Clodius. In 53, when Milo was candidate for the consulship and Clodius for the praetorship, the two leaders met by accident on the Appian Way at Bovilae and Clodius was murdered (January 52). Milo was tried for murder; his guilt was clear, and his enemies took every means of intimidating his supporters and his judges. Cicero was afraid to speak, and the extant Pro Milone is an expanded form of the unsupported defence. Milo went into exile at Massilia, and his property was sold by auction. He joined M. Cælius Rufus in 48 in his rising against Caesar, but was slain near Thurii in Lucania. His wife was Fausta, daughter of the dictator Sulla.

**MILO OF GLOUCESTER,** lord of Brecknock and earl of Hereford (d. 1143), was the son of Walter of Gloucester, who appears as sheriff of that county between 1104 and 1121. Milo succeeded his father about the latter year. He was high in the service of Henry I, between 1130 and 1135, and combined the office of sheriff with that of local justiciar for Gloucestershire. After the death of Henry I. he declared for Stephen, at whose court he appears as constable in 1136. But in 1139, when the empress Matilda appeared in England, he declared for her, and placed the city of Gloucester at her disposal; he was further distinguished by sacking the royalist city of Worcester and reducing the county of Hereford. In 1141, at Matilda's coronation, he was rewarded with the earldom of
MILORADOVICH—MILTIADES

Hereford. He remained loyal to the empress after her defeat at Winchester. John of Salisbury classes him with Geoffrey de Mandeville and others who were non tam comites regni quem hostes publici. The charge is justified by his public policy; but the materials for appraising his personal character do not exist.

See the Continuation of Florence of Worcester (ed. B. Thorpe, 1848-1849); the Cartulary of Gloucester Abbey (Rolls series); and J. H. Round's Geoffrey de Mandeville (1892).

MILORADOVICH, MICHAEL ANDRIJEVICH, Count (1770-1825), Russian general, saw service under Suvarov in the wars against Turkey and Poland, and in the campaign of Italy and Switzerland (1799) earned much distinction as a commander of advanced troops. In 1805, having attained the rank of lieutenant-general, he served under Kutusov in the campaign of Austerlitz, taking part in the actions of Enns and Krems and in the decisive battle of the 2nd of December, in which his column held the Pratzen heights. In the Turkish War he distinguished himself at Giurgevo (1807). Promoted general of infantry in 1810, he commanded a corps at Borodino, and subsequently inflicted the defeat of Tarutino (or Winkovo) on Murat, king of Naples (October 18, 1812). His corps was one of those most active in the pursuit of Napoleon's Grande Armée, and in 1813 he led the rear-guard of the Allies after their earlier defeats. At the victory of Kulm he was present in command of a Russian-Prussian corps, which he led at Leipzig and in the campaign of 1814. From 1818 to the time of his death he was military governor of St Petersburg. He perished in the popular outbreak in the capital, on the 20th (14th o.s.) of December 1825.

MILOSH OBRENOVICH I. (1780-1850), prince of Servia, founder of the Obrenovich dynasty, was born in 1780 of poor Servian peasants. When he later became prince of Servia he used to tell how for a penny a day he drove cattle from Servia to Dalmatia. His half-brother, Milan Obrenovich, who had developed into a successful exporter of cattle in Austria, associated him in his export trade and otherwise supported him. Partly from gratitude and partly because the family name of his half-brother was already honourably known in the country, Milosh adopted that name as his own, and called himself Obrenovich, instead of Theodorovich. Karageorge, the leader of the first Servian revolution against the Turks, appointed Milosh Obrenovich in 1807 a voyvode, i.e. district commander of the national army and civil administrator. As such he distinguished himself in many battles, and was reputed a wise and energetic administrator and a just judge. When in 1813 the Turks under the Grand Vizier Khurshid occupied Servia, and Karageorge and almost all his voyvodes left the country for Austria, Milosh, although strongly advised to follow their example, refused to do so. He remained in the country, surrendered to the Turks, and was recognized by them as the voyvode of Rudnik (Central Servia). As he was then practically the only chief of the nation, the Turks called him to Belgrade, where he was kept through the year 1814 as a hostage. But he found means to prepare a new rising of the Servians against the Turks, and on Palm Sunday 1815 he appeared with his voyvode's standard before the people round the small church of Takovo, and started the second and successful insurrection. Not so much by his victories on the battlefields as by his clever exploitation of the international difficulties of Turkey, and of the known weakness of the Turkish police for “bakshesh” —no doubt also by his statesmanlike moderation—he succeeded in less than two years in obtaining from the Porte the practical recognition of the Servian people's right to self-government. The National Assembly in 1817 elected him prince of Servia. From that year began the organization of Servia by the Servians as an autonomous province of the Ottoman Empire. But its existence as such rested on no safe and legal basis, except on the readiness of the Servians to defend it with all their might and on the goodwill of the sultan and his “Sublime Porte.” Milosh therefore worked hard to obtain some sort of international recognition of the semi-independent status of Servia. Russia came to his assistance, and by the Treaty of Adrianople of 1829 the Porte engaged formally to grant Servia full autonomy. This engagement was somewhat developed in the Hatti-sheer of 1830, which added to Servia three districts (Krushevats, Alexintas, Zaechar), acknowledged her full autonomy, recognized Milosh as hereditary prince of Servia, and declared that the Turks in Servia could have properties and live only in fortified places where there were Turkish garrisons, and not in other towns and villages. Milosh won for his family the hereditary right to the throne of Servia without the co-operation of Russia. The creation of a hereditary dynasty in Servia was outside the Russian Balkan policy of that time, and this great and independent success of Milosh was the first cause of Russia's dissatisfaction with him. The second cause was that, yielding to the pressure exercised on him by his own people, he gave the country a constitution without asking "the protector of Servia," the tsar, for his approval of the step. The third cause was that Milosh consistently represented the interference of Russia in the internal affairs of the principality. The climax of his misdeeds, from the Russian point of view, was that on the occasion of his visit to the Sultan Mahmud II. in 1836 he persuaded the British ambassador, Lord Ponsonby, that it would be useful to establish a British consulate in Belgrade. The first British consul in Servia, Colonel Hodges, became speedily an intimate friend of Prince Milosh, who—probably under his new friend's influence—began to agitate to replace the exclusive protectorate of Russia by the joint protectorate of all the great Powers of Europe. The cabinet of St. Petersburg now decided to remove Milosh from the throne of Servia, and, supported by the Russian consul-general, the leaders of the Servian opposition, who posed as champions of a constitutional system, succeeded in forcing him to abdicate in 1839. After his abdication Milosh lived mostly on his estates in Rumania, or in Vienna. In December 1848 the National Assembly of Servia, having deposed Prince Alexander Karageorgevich, because Milosh withdrew from the throne of Servia. Milosh came, accompanied by his son Michael, and began to reign in his own old fashion; but death closed his activity on the 14th (27th n.s.) of September 1860. He was buried in the cathedral of Belgrade. (C. M.)

MILTIADES, the name of two Athenian statesmen and generals of a family (the Philaidæ) of Aeginetan origin, which claimed descent from Aeacus.

1. Miltiades (6th century B.C.), the son of Cypselus, a prominent opponent of Peisistratus. According to Herodotus (vi. 36, 37) he led a colony to the Thracian Chersonese at the request of the Dolonians, who, hard pressed by the Abasinthians (or Apsinthians), were advised by the Delphian oracle to invite to their country the man who should first show them hospitality after leaving the temple. Since, however, the Athenians had from c. 600-590 B.C. held Sigeum in the Troad, whence they had drawn their military name, it is probable that the Dolonians appealed for help to Athens, and that Peisistratus took the opportunity of getting rid of one of his chief opponents by sending Miltiades. He became "tyrant" of the Chersonese, which he fortified with a wall across the isthmus from Cardia to Pactya. He was captured by the people of Lampsacus, but released on the intercession of Croesus of Lydia. He was succeeded by Stesagoras, son of his half-brother, Cimon.

2. Miltiades (died c. 488 B.C.), the victor of Marathon, was another son of Cimon. On the death of Stesagoras, he was sent to the Chersonese (7 about 518-516) by Hippias—no doubt to support Hegesistratus at Sigeum (see Peisistratus). He entangled and imprisoned the chief men of Chersonesus, which was then in a turbulent condition, and strengthened himself by an alliance with Hegesipyle, daughter of the Thracian prince Olorus (Herod. vi. 39). He led a contingent in the Scythian expedition of Darius Hystaspis and, according to Herodotus, advised the leaders who were left at the Danube bridge to destroy it and leave Darius to his fate. This story is improbable, as Darius left Miltiades in possession of the Chersonese for some
twenty years longer, though Persian forces were frequently in the neighbourhood. Miltiades was according to Herodotus, expelled by Scythian invaders, but was brought back by the Dolonians, and subsequently captured Lemnos and Imbros for Athens from the so-called Pelasgian inhabitants, who were Persian dependents. Having thus (probably) incurred the enmity of Darius, Miltiades fled to Athens on the approach of the Persians under Datis and Artaphernes, leaving his son Metiachus a prisoner in Persian hands, and was at once impeached unsuccessfully on the charge of tyranny in the Chersonese. 1 Possibly the story of his having tried to destroy the Danube bridge was invented or exaggerated at this time as an argument in his favour (see Grote, History of Greece, i vol., ed. 1907, p. 119 note). Since, however, Herodotus almost certainly relied on Alcmaeonid tradition, which was hostile to Miltiades, the whole story is uncertain; the statement that he fled before a Scythian invasion is especially improbable. If Miltiades really recommended the destruction of the bridge, we may infer that the Herodotean story of his flight before the Scythisans is a misunderstanding of the fact that his residence in Chersonese after the Scythian invasion was insecure and not continuous.

On the approach of the Persians Miltiades was made one of the ten Athenian generals, and it was on his advice that the polemarch Callimachus decided to give battle at Marathon (q.v.). Subsequently he used his influence with the Athenians to induce them to give him a fleet of seventy ships without any indication of his object (Herod. vi. 132-136). Cornelius Nepos (Miltiades, c. vii.), probably on good authority (Ephorus), states that he had a commission to regain control over the Aegean. No doubt his object was to establish an outer line of defence against future Persian aggression. Herodotus says that, having besieged Paros vainly for nearly a month, he made a secret visit to Timo, a priestess of Demeter in Paros, with a view to the betrayal of the island, and being compelled to flee wounded himself severely in attempting to leap a fence (but see Ephorus in Fragm. hist. gr. 107).

On his return to Athens he was impeached by Xanthippus, who was allied by marriage to the Alcmaeonids, on the ground that he had “deceived the people,” and only escaped on the strength of his past services with a fine of 50 talents. The facts of the trial and the charge are difficult to recover, nor do we know why the siege was raised. Some authorities hold that he was bribed to this course, and hence that the charge was one of treason; others suggest that he retired in the belief that a Persian fleet was approaching. All that is known is that he died of his wound (489-488), without paying the fine, which was paid subsequently by his son Cimon (q.v.). He appears to have been a man of strong determination and great personal courage, of a type characteristic of the pre-Cleisthenic constitution. His absence in the Chersonese during the first years of the new democracy (508-493?) and his patrician lineage account naturally for the difference which existed between him and the popular leaders—Themistocles and Aristides—of the next generation. See the passage of Herodotus and Cornelius Nepos quoted above, and histories of Greece. On the Parian expedition and the trial, R. W. Macan, Herodotus iv.-vi., vol. 2, appendix xi.; on the foreign policy of Miltiades see Themistocles. (J. M. M.)

Milton, John (1608-1674), English poet, was born in Bread Street, Cheapside, London, on the 9th of December 1608. His father, known as Mr John Milton of Bread Street, scrivener, was himself an interesting man. He was a native of Oxfordshire, the son of a Richard Milton, yeoman of Stanton-St-John's, one of the sturdy adherents to the old Roman Catholic religion in his district. He was educated at Christ Church, Oxford, where he turned Protestant. According to the poet's earliest biographer, John Milton senior was disinherited in the beginning of Queen Elizabeth's reign for reading the Bible. With a good education and good abilities, especially in music, he may have lived for some time in London by musical teaching and practice.

1 So Herodotus; but the story is difficult to believe in view of the fact that the family of Miltiades was distinctively -acarpus. Possibly the trial is merely a heretical version of the ordinary test of a man's qualification for office (καταποιησας).

Not till 1555, at all events, when he must have been long past the usual age of apprenticeship, do we hear of his preparation for the profession of a scrivener, and not till February 1569-70, when he was about thirty-seven years of age, did he become a qualified member of the Scrivener's Company. It was then that he set up his "house and shop" at the sign of the Spread Eagle in Bread Street, and began his business of drawing up wills, marriage-settlements, and the like, with such related business as that of receiving money from clients for investment and lending it out to the best advantage. It was at the same time that he married, not, as stated by Aubrey, a lady named Bradshaw, but Sarah Jeffrey, one of two orphan daughters of a Paul Jeffrey, of St Swithin's, London, "citizen and merchant-taylor," originally from Essex, who had died before 1585. At the date of her marriage she was about twenty-eight years of age. Six children were born to the scrivener and his wife, of whom three survived infancy—Anne, who married Edward Phillips; John, the poet; and Christopher (1615-1693), who was knighted and made a judge under James II.

The first sixteen years of Milton's life, coinciding exactly with the last sixteen of the reign of James I., associate themselves with the house in Bread Street. His father, while prospering in business, continued to be known as a man of "ingenious" tastes, and acquired distinction in the London musical world of that time. He contributed a madrigal to Thomas Morley's Triumph of Oriana (1601), four motets to Sir William Leighton's Tears and Lamentations of a Sorrowsful Soul (1614), and some hymn tunes—one of which, "Yor," is still in common use—in Thomas Ravenscroft's Whole Book of Psalms (1621). Music was thus a part of the poet's domestic education from his infancy. Again and again Milton speaks with gratitude and affection of the ungrudging pains bestowed by his father on his early education. "Both at the grammar school and also under other masters at home," is the statement in one passage, "he caused me to be instructed daily." When Milton was ten years of age his tutor was Thomas Young (1587-1655), a Saxon, who with divinity was called master of Jesus College, Cambridge. Young's tuition lasted till 1622, when he accepted the pastorate of the congregation of English merchants in Hamburg. Already, however, for a year or two his teaching had been only supplementary to the education which the boy was receiving by daily attendance at St Paul's public school, close to Bread Street. The head-master of the school was Alexander Gill, an elderly Oxford divine, of high reputation for scholarship and teaching ability. Under him, as usher or second master, was his son, Alexander Gill the younger, also an Oxford graduate of scholarly reputation, but of blustering character. Milton's acquaintance with this younger Gill, begun at St Paul's school, led to subsequent friendship and correspondence. Far more affectionate and intimate was the friendship formed by Milton at St Paul's with his schoolfellow Charles Diodati, the son of an Italian physician, Dr Thomas Diodati, a naturalized Englishman, who taught at St Paul's, London, and much respected, both on his own account and as being the brother of the famous Protestant divine, John Diodati of Geneva. Young Diodati, who was destined for his father's profession, left the school for Trinity College, Oxford, early in 1623; but Milton remained till the end of 1624. In that year his elder sister, Anne, married Edward Phillips, a clerk in the Government office called the Crown Office in Chancery.

Milton had then all but completed his sixteenth year, and was as scholarly, as accomplished and as handsome a youth as St Paul's school had sent forth. We learn from himself that his exercises "in English or other tongue, prosing or versing, but chiefly this latter," had begun to attract attention even in his boyhood. Of these poems the only specimens that now remain are two copies of Latin verses, preserved in a commonplace book of his (printed by the Camden Society in 1877), and his "Paraphrase on Psalm CXI" and his "Paraphrase on Psalm CXXXVI." At the age of sixteen years and two months, Milton was entered as a student of Christ's College, Cambridge.
in the grade of a "Lesser Pensioner," and he matriculated two months later, on the 9th of April 1625. The master of Christ's was Dr Thomas Bainbrigge; and among the thirteen fellows were Joseph Meade, still remembered as a commentator on the Apocalypse, and William Chappell, afterwards an Irish bishop. It was under Chappell's tutelage that Milton was placed when he first entered the college. At least three students who entered Christ's after Milton, but during his residence, deserve mention. One was Edward King, a youth of Irish birth and high Irish connexions, who entered in 1626, at the age of fourteen, another was John Cleveland, afterwards known as royalist and satirist, who entered in 1627; and the third was Henry More, subsequently famous as the Cambridge Platonist, who entered in 1631, just before Milton left. Milton's own brother, Christopher, joined him in the college in February 1636-1637, at the age of fifteen.

Milton's academic course lasted seven years and five months, bringing him from his seventeenth year to his twenty-fourth. The first four years were his time of undergraduateship. It was in the second of these—the year 1626—that there occurred the quarrel between him and his tutor, Chappell, which Dr Johnson, making the most of a lax tradition from Aubrey, magnified into the supposition that Milton may have been one of the last students in either of the English universities that suffered the indignity of corporal punishment. The legend deserves no credence; but it is certain that Milton, on account of some disagreement with Chappell, left college for a time, though he did not lose his term; and that when he did return, he was transferred from the tutorship of Chappell to that of Nathaniel Tovey. From the first of the Latin elegies one infers that the cause of the quarrel was some outbreak of self-assertion on Milton's part. We learn indeed, from words of his own elsewhere, that it was not only Chappell and Bainbrigge that he had offended by his independent demeanour, but that, for the first two or three years of his undergraduateship, he was generally unpopular, for the same reason, among the younger men of his college. They had nicknamed him "the Lady"—a nickname which the students of the other colleges took up, converting it into "the Lady of Christ's"; and, though the allusion was chiefly to the peculiar grace of his personal appearance, it conveyed also a sneer at what the rougher men thought his unusual prudishness, the haughty fastidiousness of his tastes and morals. A change in this state of things had certainly occurred before January 1628-1629, when, at the age of twenty, he took his B.A. degree. By that time his intellectual preeminence had come to be acknowledged. His reputation for scholarship and literary genius, extraordinary even then, was confirmed during the remaining three years and a half of his residence in Cambridge. A fellowship in Christ's which fell vacant in 1630 would undoubtedly have been his had the election to such posts depended then absolutely on merit. As it was, the fellowship was conferred, by royal favour on Edward King, his junior in college standing by sixteen months. In July 1632 Milton completed his career at the university by taking his M.A. degree. Tradition still points out Milton's rooms at Christ's College. They are on the first floor on the first stair on the north side of the great court.

Of Milton's skill at Cambridge, in what Wood calls "the collegiate and academical exercises," specimens remain in his Prologiae quaedam orationis. They consist of seven rhetorical Latin essays, generally in a whimsical vein, delivered by him, either in the hall of Christ's College or in the public university, during Milton's Cambridge period, the greater number of his Latin "Familiar Epistles," and the greater number of his preserved Latin poems, including: (1) the seven pieces, written in 1626, which compose his Epigrammata liber, two of the most interesting of them addressed to his friend, Charles Diodati, and one to his former tutor, Young, in his exile at Hamburg; (2) the five short Gunpowder Plot epigrams, now appended to the Elegies; and (3) the first five pieces of the Sylva liber, the most important of which are the hexameter poem "In quinuaginta mensibus" (1626), and the piece entitled Natum non pati seminum (1628). Of the English poems of the Cambridge period the following is a dated list: "On the Death of a fair Infant" (1625-1626), the subject being the death of the first-born child of his sister Anne Phillips; "At a Vacation Exercise in the College" (1628), the magnificent Christmas ode; "On the Morning of Christ's Nativity" (1629); the fragment called "The Passion" and the "Song on May Morning," both probably belonging to 1630; the sonnet "On Shakespeare," certainly belonging to that year, printed in the Shakespeare folio of 1623; the two facetious pieces "On the University Carrier" (1630-1631); the "Epitaph on the Marchioness of Winchester" (1631); the sonnet "To the Nightingale," probably of the same year; the sonnet "On arriving at the Age of twenty-three," dating itself certainly in December 1631.

Just before Milton quitted Cambridge, his father, then verging on his seventieth year, had practically retired from his Bread Street business, leaving the active management of it to a partner, named Thomas Bower, a former apprentice of his, and had gone to spend his declining years at Horton in Buckinghamshire, a small village near Colnbrook, and not far from Windsor. Here, in a house close to Horton church, Milton mainly resided for the next six years— from July 1632 to April 1638.

Although, when he had gone to Cambridge, it had been with the intention of becoming a clergyman, that intention had been abandoned. His reasons were that "tyranny had invaded the church," and that, finding he could not honestly subscribe the oaths and obligations required he "thought it better to preserve a blameless silence before the sacred office of speaking, begun with servitude and forswearing." In other words, he was disgusted with the system which Laud was establishing and maintaining in the Church of England. "Church-outed by the prelates," as he emphatically expresses it, he seems to have thought for a time of the law, but he decided that the only life possible for himself was one dedicated wholly to scholarship and literature. His compositions on this subject, expressed already in his sonnet on arriving at his twenty-third year, are expressed more at length in an English letter of which two drafts are preserved in Trinity College, Cambridge, sent by him, shortly after the date of that sonnet, and with a copy of the sonnet included, to some friend who had been remonstrating with him on his "believeth and his persistence in a life of mere dream and study. There were gentle remonstrances also from his excellent father. Between such a father and such a son, however, the conclusion was easy. What it was may be learnt from Milton's fine Latin poem Ad patrem. There, in the midst of an enthusiastic recitation of all that his father had done for him hitherto, it is intimated that the agreement between them on their one little matter of difference was already complete, and that, as the son was bent on a private life of literature and poetry, it had been decided that he should have his own way, and should in fact, so long as he chose, be the master of his father's means and the chief person in the Horton household. For the six years from 1632 this, accordingly, was Milton's position. In perfect leisure, and in a pleasant rural retirement, with Windsor at the distance of an easy walk, and London only about 17 m. off, he went through, he tells us, a systematic course of reading in the Greek and Latin classics, varied by mathematics, music, and the kind of physical science we should now call cosmography.

It is an interesting fact that Milton's very first public appearance in the world of English authorship was in so honourable a place as the second folio edition of Shakespeare in 1632. His enthusiastic eulogy on Shakespeare, written in 1630, was one of the most important of his early writings. Among the poems actually written by Milton at Horton, the first, in all probability, after the Latin hexameters Ad patrem, were the exquisite companion pieces L'Allegro and Il Penseroso. There followed, in or about 1633, the fragment called Arcades. It was part of a pastoral masque performed by the young people of the noble family of Egerton before the countess-dowager

1 See the preface to Book II. of his Reason of Church Government (1641-1642), which is of great biographical interest.\n
18. 16
of Derby, at her mansion of Harefield, about 10 m. from Horton. That Milton contributed the words for the entertainment was, almost certainly, owing to his friendship with Henry Lawes, who supplied the music. Next in order among the composition of the Horton may be mentioned the three short pieces: “At a Sollem Music,” “On Time,” and “Upon the Circumcision”; after which comes Comus, the largest and most important of all Milton’s minor poems. The name by which that beautiful drama is now universally known was not given to it by Milton himself. He entitled it, more simply and vaguely, “A Masque presented at Ludlow Castle, 1634, on Michaelmas night, before John Earl of Bridgewater, Lord President of Wales” (1637). The Earl of Bridgewater, the head of the Egerton family, had been appointed president of the council of Wales; among the festivities on his assumption of the office, a great masque was arranged in the hall of Ludlow Castle, his official residence. Lawes supplied the music and was stage manager; he applied to Milton for the poetry; and on Michaelmas night, the 29th of September 1634, the drama furnished by Milton was performed at Ludlow Castle before a great assemblage of the nobility and gentry of the Welsh principality, Lawes taking the part of “the attendant spirit,” while the parts of “first brother,” “second brother” and “the lady,” were taken by the Earl’s three youngest children, Viscount Brackley, Mr. Thomas Egerton and Lady Alice Egerton.

From September 1634 to the beginning of 1637 is a comparatively blank in our records. Struggling incidents in this blank are suggested by a letter of date December 4, 1634, to Alexander Gill the younger, a Greek translation of “Psalm CXIV.” a visit to Oxford in 1635 for the purpose of incorporation in the degree of M.A. in that university, and the beginning in May 1636 of a troublesome lawsuit against his now aged and infirm father. The lawsuit, which was instituted by a certain Sir Thomas Cotton, bart., nephew and executor of a deceased John Cotton, Esq., accused the elder Milton and his partner Bower, or both, of having, in their capacity as scriveners, misappropriated divers large sums of money that had been entrusted to them by the deceased Cotton to be let out at interest.

The lawsuit was still in progress when, on the 3rd of April 1637, Milton’s mother died, at the age of about sixty-five. A flat blue stone, with a brief inscription, visible on the chancel-pavement of Horton church, still marks the place of her burial. Milton’s testimony to her character is that she was “a most excellent mother and particularly known for her charities through the neighbourhood.” The year 1637 was otherwise eventful. It was in that year that his Comus, after lying in manuscript for more than two years, was published by itself, in the form of a small quarto of thirty-five pages. The author’s name was withheld, and the entire responsibility of the publication was assumed by Henry Lawes. Milton seems to have been in London when the little volume appeared. He was a good deal in London, at all events, during the summer and autumn months immediately following his mother’s death. The plague, which had been on one of its periodical visits of ravage through England since early in the preceding year, was then especially severe in the Horton neighbourhood, while London was comparatively free. It was probably in London that Milton heard of the death of Edward King, who had sailed from Chester for a vacation visit to his relatives in Ireland, when, on the 20th of August, the ship in perfectly calm water struck on a rock and went down, and nearly all the other passengers going down with her. There is no mention of this event in Milton’s two Latin “Familiar Epistles” of September 1637, addressed to his friend Charles Diodati, and dated from London; but in November 1637, and probably at Horton, he wrote his matchless pastoral melody of Lycidas. It was his contributia to a collection of obituary verses, Greek, Latin and English, inscribed to the memory of Edward King by his numerous friends, at Cambridge and elsewhere. The collection appeared early in 1638. The second part contained thirteen English poems, the last of which was Milton’s monody, signed only with his initials “ J. M.”

Milton was then on the wing for a foreign tour. He had long set his heart on a visit to Italy, and circumstances now favoured his wish. The vexatious Cotton lawsuit, after hanging on for nearly two years, was, at an end, as far as the elder Milton was concerned, with the publication of his defence, and the honourable vindication of his character for probity, though with some continuation of the case against his partner, Bower. Moreover, Milton’s younger brother Christopher, though but twenty-two years of age, and just about to be called to the bar of the Inner Temple, had married; and the young couple had gone to reside at Horton to keep the old man company.

Before the end of April 1638 Milton was on his way across the channel, taking one English man-servant with him. At the time of his departure the last great news in England was that of the National Scottish Covenant. To Charles the news of this “damnable Covenant,” as he called it, was enraging beyond measure; but to the mass of the English Puritans it was far from unwellcome, promising, as it seemed to do, for England herself, the subversion at last of that system of “Thorough,” or despotic government by the king and his ministers without parliaments, under which the country had been groaning since the contemptuous dissolution of Charles’s third parliament ten years before. Through Paris, where Milton received polite attention from the English ambassador, Lord Scudamore, and had the honour of an introduction to the famous Hugo Grotius, then ambassador for Sweden at the French court, he moved on rapidly to Italy, by way of Nice. After visiting Genoa, Leghorn and Pisa, he arrived at Florence, in August 1638. Enchanted by the city and its society, he remained there two months, frequenting the chief academies or literary clubs, and even taking part in their proceedings. Among the Florentines with whom he became intimate were Jacopo Gaddi, founder of an academy called the Svolgiati, young Carlo Dati, author of Vitae de’ pitori antichi, Pietro Frescobaldi, Agostino Coltellini, the founder of the Academy of the Apastisi, the grammarian Benedetto Buonmattei, Valerio Chimentelli, afterwards professor of Greek at Pisa, Antonio Francini and Antonio Malatatesti. It was in the neighbourhood of Florence also that he “found and visited” the great Galileo, then old and blind, and still nominally a prisoner to the Inquisition for his astronomical heresy.1

By way of Florence and Siena, he reached Rome some time in October, and spent about another two months there, not only going about among the ruins and antiquities and visiting the galleries, but mixing also, as he had done in Florence, with the learned society of the academies. Among those with whom he formed acquaintance in Rome were the German scholar, Lucas Holstenius, librarian of the Vatican, and three native Italian scholars, named Alessandro Cherubini, Giovanni Salzilli and a certain Selvaggi. There is record of his having dined once, in company with several other Englishmen, at the hospitable table of the English Jesuit College. The most picturesque incident, however, of his stay in Rome was his presence at a great musical entertainment in the palace of Cardinal Francesco Barberini. Here he had not only the honour of a specially kind reception by the cardinal himself, but also, it would appear, the supreme pleasure of listening to the marvellous Leonora Baroni, the most renowned singer of her age.

Late in November he left Rome for Naples. Here he met the aged Giovanni Battista Manso, marquis of Villa (1560–1645), the friend and biographer of Tasso, and subsequently the friend and patron of Marini. He had hardly been in Naples a month, however, when there came news from England which not only stopped an intention he had formed of extending his tour to Sicily and thence into Greece, but urged his immediate return home. “The sad news of civil war in England,” he says, “called me back; for I considered it base that, while my fellow-countrymen were fighting at home for liberty, I should be travelling at my ease for intellectual culture” (Defensio Secunda). In December 1638, therefore, he set his face northwards

1This interview forms the subject of one of W. S. Landor’s Imaginary Conversations.
again. His return journey, however, probably because he learnt that the news he had first received was exaggerated or premature, was broken into stages. He spent a second January and February (1638–1639) in Rome, in some danger, he says, from the papal police, because the English Jesuits in Rome had taken offence at his habit of free speech, wherever he went, on the subject of religion. From Rome he went to Florence, his second visit to the city, including an excursion to Lucca, extending over two months; and not till April 1639 did he take his leave, and proceed, by Bologna and Ferrara, to Venice. About a month was given to Venice; and thence, having shipped for England the books he had collected in Italy, he went on, by Verona and Milan, over the Alp, to Geneva. In this Protestant city he spent a week or two in June, forming interesting acquaintance there too, and having daily conversations with the great Protestant theologian Dr Jean Diodati, the uncle of his friend Charles Diodati. From Geneva he returned to Paris, and so to England. He was home again in August 1639, having been absent in all fifteen or sixteen months.

Milton's Continental tour, and especially the Italian portion of it, which he describes at some length in his Defensio secunda, remained one of the chief pleasures of his memory through all his subsequent life. Nor was it without fruits of a literary kind. Besides two of his Latin Epistolae familiares, one to the Florentine grammarian Buonmattei, and the other to Lucas Holstienius, there have to be assigned to Milton's sixteen months on the Continent his three Latin epigrams Ad Leonoram Romae consecutum, his Latin sonatas Ad Salmisum poema romanum aegrotanum, his fine Latin hexameters entitled Manus, addressed to Giovanni Battista Mano, and his five Italian sonnets, with a canzone, in praise of a Bolognese lady.

His bosom friend and companion from boyhood, Charles Diodati, died in Blackfriars, London, in August 1638, not four months after Milton had gone away on his tour. The intelligence did not reach Milton till some months afterwards, probably not till his second stay in Florence; and, though he must have learnt some of the particulars from his friend's uncle in Geneva, he did not know them fully till his return to England. How profoundly they affected him appears from his Epitaphium Damonis, then written in memory of his dead friend. The importance of this poem in Milton's biography cannot be overstated. It is perhaps the noblest of all his Latin poems; and, though written in the artificial manner of a pastoral, it is unmistakably an outburst of the most passionate personal grief. In this respect Lycidas, artistically perfect though that poem is, cannot be compared with it; and it is only the fact that Lycidas is in English, while the Epitaphium Damonis is in Latin, that has led to the notion that Edward King of Christ's College was peculiarly and pre-eminently the friend of Milton in his youth and early manhood.

We should not have known, but for an incidental passage in the Epitaphium Damonis, that, at the time of his return from Italy, he had chosen a subject for a great poem from the Arthurian legend. The passage (lines 160–178) is one in which, after referring to the hopes of Diodati's medical career so suddenly cut short by his death, Milton speaks of himself and of his own projects in his profession of literature. Milton wrote that he was meditating an epic of which King Arthur was to be the central figure, but which should include somehow the whole cycle of British and Arthurian legend. This epic was to be in English, and he had resolved that all his poetry for the future should be in the same tongue. But not long after his return to the home he had made at Horton ceased to be the family home, Christopher Milton and his wife went to reside at Reading, taking the old gentleman with them, while Milton himself preferred London. He had first taken lodgings in St Bride's Churchyard, at the foot of Fleet Street; but, after a while, probably early in 1640, he removed to a "pretty garden house" of his own, at the end of an entry, in the part of Aldersgate Street which lies immediately on the city side of what is now Maidenhead Court. His sister, whose first husband had died in 1631, had married a Mr. Thomas Agar, his successor in the Crown Office; and it was arranged that her two sons by her first husband should be educated by their uncle. John Phillips, the younger of them, only nine years old, had boarded with him in the St Bride's Churchyard lodgings; and, after the removal to Aldersgate Street, the other brother, Edward Phillips, only a year older, became his boarder also. Gradually a few other boys, the sons of well-to-do personal friends, joined the two Philipps, whether as boarders or for daily lessons, so that the house in Aldersgate Street became a small private school.

The Arthurian epic had been given up, and his mind was roving among many other subjects, and balancing their capabilities. How he wavered between Biblical subjects and heroic subjects from British history, and how many of each kind suggested themselves to him, one learns from a list in his own handwriting among the Milton MSs at Cambridge. It contains lodgings of no fewer than fifty-three subjects from the Old Testament, eight from the Gospels, thirty-three from British and English history before the Conquest, and five from Scottish history. It is curious that all or most of them are headed or described as subjects for "tragedies," as if the epic form had now been abandoned for the dramatic. There are four separate drafts of a possible tragedy on the Greek model under the title of Paradise Lost, two of them merely enumerating the dramatis personae, but the last two indicating the plot and the division into acts. In 1641 he wrote in the Reason of Church Government that he was meditating a poem on high moral or religious subjects. But the fulfilment of these plans was indefinitely postponed. Milton became absorbed in the ecclesiastical controversies following on the king's attempt to force the episcopal system on the Scots.

Of the first proceedings of the Long Parliament, including the trial and execution of Strafford, the impeachment and imprisonment of Laud and others, and the breakdown of the system of Thorough by miscellaneous reforms and by guarantees for parliamentary liberty, Milton was only a spectator. It was when the church question emerged distinctly as the question paramount, and there had arisen divisions on that question among those who had been practically unanimous in matters of civil reform, that he plunged in as an active adviser. There were three parties on the church question. There was a high-church party, contending for episcopacy by divine right, and for the maintenance of English episcopacy very much as it was; there was a middle party, defending episcopacy on grounds of usage and expediency, but desiring to see the powers of bishops greatly curtailed, and a limited episcopacy, with councils of presbyters round each bishop, substituted for the existing high episcopacy; and there was the root-and-branch party, as it called itself, desiring the entire abolition of episcopacy and the reconstruction of the English Church on something like the Scottish Presbyterian model. Since the opening of the parliament there had been a storm of pamphlets from these three parties. The manifesto of the high-church party was a pamphlet by Joseph Hall, bishop of Exeter, entitled "Humble Remonstrance to the High Court of Parliament." In answer to Hall, and in representation of the views of the root-and-branch party, there had stepped forth, in March 1640–1641, five leading Puritan parish ministers, the initials of whose names, clubbed together on the title-page of their joint production, made the uncouth word "Smectymnuus." These were Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen and William Spurstow. Thomas Young was the Scottish divine who had been Milton's tutor in Bread Street in 1628, and had returned from Hamburg in 1638, and had been appointed to the vicarage of Stowmarket in Suffolk. The famous Smectymnuan pamphlet in reply to Hall was mainly Young's. What is more interesting is that his old pupil Milton was secretly in partnership with him and his brother-Smecktmnuans. Milton's hand is discernible in a portion of the original Smectymnuan pamphlet; and he continued to aid the Smectymnuans in their subsequent rejoinders to Hall's defences.
of himself. In May 1641 he put forth a defence of the Smectymnuan side in Of Reformation touching Church Discipline in England and the Causes that hitherto have hindered it. He reviewed English ecclesiastical history, with an appeal to his countrymen to resume that course of reformation which he considered to have been prematurely stopped in the preceding century, and to sweep away the last relics of papacy and prelacy. Among all the root-and-branch pamphlets of the time it stood out, and stands out still, as the most thorough-going and tremendous. It was followed by four others in rapid succession, and it was directed chiefly against that middle party which advocated a limited episcopacy, with especial reply to the arguments of Archbishop Ussher, as the chief exponent of the views of that party. Two of the others, as the titles imply, belong to the Smectymnuan series, and were castigations of Bishop Hall. The greatest of the four, and the most important of all Milton's anti-episcopal pamphlets after the first, is that entitled The Reason of Church Government. It is there that Milton takes his readers into his confidence, speaking at length of himself and his motives in becoming a controversialist. Poetry, he declares, was his real vocation; it was with reluctance that he had resolved to "leave a calm and pleasing solitariness, fed with cheerful and confident thoughts, to embark in a troubled sea of noises and hoarse disputes"; but duty had left him no option. The great poem or poems he had been meditating could wait; and meanwhile, though in prose-polonies he had the use only of his "left hand," that hand should be used with all its might in the cause of his country and his God. The Apology was in answer to a Modest Confutation of a Slanderous and Scurrilous Libel, the joint work of Hall and his son, attacking Milton's personal character.

The parliament had advanced in the root-and-branch direction so far as to have passed a bill for the exclusion of bishops from the House of Lords, and compelled the king's assent to that bill, when, in August 1642, the further struggle between Charles and his subjects took the form of civil war. The Long Parliament moved on more and more rapidly in the root-and-branch direction, till, by midsummer 1643, the abolition of episcopacy had been decreed, and the question of the future non-prelatical constitution of the Church of England referred to a synod of divines, to meet at Westminster under parliamentary authority. Of Milton's life through those first months of the Civil War little is known. He remained in his house in Aldersgate Street, teaching his nephews and other pupils; and the only scrap that came from his pen was the semi-jocose sonnet bearing the title "When the Assault was intended to the City." In the summer of 1643, however, there was a great change in the Aldersgate Street household. About the end of May, as his nephew Edward Phillips remembered, Milton went away on a country journey, without saying whither or for what purpose; and, when he returned, about a month afterwards, it was with a young wife, and with some of her sisters and other relatives in her company. He had, in fact, been in the very headquarters of the king and the Royalist army in and round Oxford; and the bride he brought back with him was a Mary Powell, the eldest daughter of Richard Powell, of Forest Hill, near Oxford. She was the third of a family of eleven sons and daughters, of good standing, but in rather embarrassed circumstances, and was seventeen years and four months old, while Milton was in his thirty-fifth year. However the marriage came about, it was a most unfortunate event. The Powell family were strongly Royalist, and the girl herself seems to have been frivolous, and entirely unsuited for the studious life in Aldersgate Street. Hardly were the honeymoon festivities over, when, her sisters and other relatives having returned to Forest Hill and left her alone with her husband, she pined for home again and begged to be allowed to go back on a visit. Milton consented, on the understanding that the visit was to be a brief one. This seems to have been in July 1643. Soon, however, the intimation from Forest Hill was that he need not look ever to have his wife in his house again. The resolution seems to have been mainly the girl's own; but, as the king's cause was then prospering in the field, Edward Phillips was probably right in his conjecture that the whole of the Powell family had repented of their sudden connexion with so prominent a Parliamentarian and assailant of the Church of England as Milton. While his wife was away, his old father, who had been residing for three years with his younger and lawyer son at Reading, came to take up his quarters in Aldersgate Street.

Milton's conduct under the insult of his wife's desertion was most characteristic. Always fearless and speculative, he converted his own case into a public protest against the existing law and the theory of marriage. To Doctrine and Discipline of Divorce, Restored to the Good of both Sexes from the Bondage of Canon Law and other Mistakes was the title of a pamphlet put forth by him in August 1643, without his name, but with no effort at concealment, declaring the notion of a sacramental sanctity in the marriage relation to be a clerically invented superstition, and arguing that inherent incompatibility of character, or contrariety of mind, between two married persons is a perfectly just reason for divorce. If the date, the 1st of August, is correct, the pamphlet must have been written almost immediately on his wife's departure and before her definite refusal to return. There was no reference to his own case, except by implication; but the boldness of the speculation roused attention and sent a shock through London. It was a time when the authors of heresies of this sort, or of any sort, ran considerable risks. The famous Westminster Assembly of Divines, called by the Long Parliament, met on the 1st of July 1643. Whether Milton's divorce tract was formally discussed in the Assembly during the first months of its sitting is unknown; but it is certain that the London clergy, including not a few members of the Assembly, were then angrily discussing it in private. That there might be no obstacle to a more public prosecution, Milton put his name to a second and much enlarged edition of the tract, in February 1644, dedicated openly to the parliament and the assembly. Then, for a month or two, during which the gossip about him and his monstrous doctrine was spreading more and more, he turned his attention to other subjects.

Among the questions in agitation in the general ferment of opinion brought about by the Civil War was that of a reform of the national system of education and especially of the universities. To this question Milton made a contribution in June 1644, in a small treatise, Of Education, in the form of a letter to Samuel Hartlib, a German then resident in London and interesting himself busily in all philanthropic projects and schemes of social reform. In the very next month, however, July 1644, he returned to the divorce subject in a pamphlet addressed specially to the clergy and entitled The Judgment of Martin Bucer concerning Divorce. The outcry against him then reached its height. He was attacked in pamphlets; he was denounced in pulpits all through London, and especially by Herbert Palmer in a sermon preached on the 13th of August, before the two Houses of Parliament; strenuous efforts were made to bring him within definite parliamentary censure. In the cabal formed against him for this purpose a leading part was played, at the instigation of the clergy, by the Stationers' Company of London, which had a plea of its own against him on the ground that his doctrine was not only immoral, but had been put forth in an illegal manner. His first divorce treatise, though published immediately after the "Printing Oath," of the parliament of the 14th of June 1643, requiring all publications to be licensed for press by one of the official censors, and to be registered in the books of the Stationers' Company, had been issued without license and without registration. Complaint to this effect was made against Milton, with some others
liable to the same charge of contempt of the printing ordinance, in a petition of the Stationers of the House of Commons in August 1644; and the matter came before committee both in that House and in the Lords.

It is to this circumstance that the world owes the most popular and eloquent, if not the greatest, of all Milton's prose writings, his famous Areopagitica, a Speech of Mr John Milton for the Liberty of Unlicensed Printing, to the Parliament of England. It appeared on the 25th of November 1644, deliberately unlicensed and unregistered, and was a remonstrance addressed to the parliament, as in an oration to them face to face, against their ordinance of June 1643 and the whole system of licensing and censorship of the press. Nobly eulogistic of the parliament in other respects, it denounced their printing ordinance as utterly unworthy of them, and of the new era of English liberties which they were initiating, and called for its repeal. Though that effect did not follow, the pamphlet virtually accomplished its purpose. The licensing system had received its death-blow; and, though the Stationers returned to the charge in another complaint to the House of Lords, Milton's offence against the press ordinance was condoned.

He was still assailed in pamphlets, and found himself "in a world of diseasement"; but he lived on through the winter of 1644/5 undisturbed in his house in Aldersgate Street. To this period there belong, in the shape of verse, only his sonnets ix. and x., the first to some anonymous lady, and the second "to the Lady Margaret Ley," with perhaps the Greek lines entitled Philosophus ad regem quendam. His divorce speculation, however, still occupied him; and in March 1645/6 he published simultaneously his Tetrachordon: Expositions upon the four chief places of Scripture which treat of Marriage, and his Colasterson, A Reply to a nameless Answer against the Doctrine and Discipline of Divorce. In these he replied to his chief recent assailants, lay and clerical, with merciless severity.

Through the latter part of 1644, Milton had been saved from the penalties under which his Presbyterian opponents would have inflicted on him by the general championship of liberty of opinion by Cromwell and the army Independents. Before the middle of 1645 he, with others who were on the black books of the Presbyterians as heretics, was safer still. Milton's position before the battle of Naseby may be easily understood. Though his first tendency on the Church question had been to some form of a Presbyterian constitution for the Church, he had parted utterly now from the Scots and Presbyterians, and become a partisan of Independency, having no dread of "sects and schisms," but regarding them rather as healthy signs in the English body-politic. He was, indeed, himself one of the most noted sectaries of the time, for in the lists of sects drawn out by contemporary Presbyterian writers special mention is made of one small sect which were known as Miltonists or Divorcers.

So far as Milton was concerned personally, his interest in the divorce speculation came to an end in July or August 1645, when, by friendly interference, a reconciliation was effected between him and his wife. The ruin of the king's cause at Naseby had suggested to the Powells that it might be as well for their daughter to go back to her husband after their two years of separation. It was not, however, in the house in Aldersgate Street that she rejoined him, but in a larger house, which he had taken in the adjacent street called Barbican, for the accommodation of an increasing number of pupils.

The house in Barbican was tenanted by Milton from about August 1645 to September or October 1647. Among his first occupations there must have been the revision of the proof sheets of the first edition of his collected poems. It appeared as a tiny volume, copies of which are now very rare, with the title, Poems of Mr John Milton, both English and Latin, compos'd at several times. Printed by his true Copies. The songs were set in Musick by Mr Henry Lawes. . . The title-page gives the date 1645, but the 2nd of January 1645/6 seems to have been the exact day of its publication. Whether because his pedagogic duties now engrossed him or for other reasons, very few new pieces were added in the Barbican to those that the little volume had thus made public. In English, there were only the four sonnets now numbered xi.-xiv., the first two entitled "On the Detraction which followed upon my writing certain Treatises," the third "To Mr Henry Lawes on his Airs," and the fourth "To the Religious Memory of Mrs Catherine Thomson," together with the powerful anti-Presbyterian invective or "tailed sonnet" entitled "On the New Forces of Conscience under the Long Parliament," and in Latin there were only the ode Ad Joannem Rousium, the Apologus de Rustico et Hero, and one interesting "Familiar Epistle" (April 1647) addressed to his Florentine friend Carlo Dati.

Some family incidents of importance belong to this time of residence in Barbican. The fall of Oxford in 1646 compelled the whole of the Powell family to seek refuge in London, and most of them found shelter in Milton's house. His first child, a daughter named Anne, was born there on the 29th of July that year; on the 1st of January 1646/7 his father-in-law Richard Powell died there, leaving his affairs in confusion; and in the following March his own father died there, at the age of eighty-four, and was buried in the adjacent church of St Giles, Cripplegate.

From Barbican Milton removed, in September or October 1647, to a smaller house in that part of High Holborn which adjoins Lincoln's Inn Fields. His Powell relatives had now left him, and he had reduced the number of his pupils, or perhaps kept only his two nephews. But, though thus more at leisure, he did not yet resume his projected poem, but occupied himself rather with three works of scholarly labour which he had already for some time had on hand. One was the compilation in English of a complete history of England, or rather of Great Britain, from the earliest times; another was the preparation in Latin of a complete system of divinity, drawn directly from the Bible; and the third was the collection of materials for a new Latin dictionary. Milton had always a fondness for such labours of scholarship and compilation. Of a poetical kind there is nothing to record, during his residence in High Holborn, but an experiment in psalm-translation, in the shape of Ps. lxxx.-lxxviii., done into service-metre in April 1648, and the sonnet to Fairfax, written in September of the same year.

The crushing defeat of the Scottish army by Cromwell in the three days' battle of Preston (1648) and the simultaneous suppression of the English Royalist insurgents in the south-east counties by Fairfax's siege and capture of Colchester, left King Charles at the mercy of the victors. Milton's sonnet "On the Lord General Fairfax, at the siege of Colchester," attested the exultation of the writer at the triumph of the parliamentary cause. His exultation continued through what followed. When the king was beheaded (1649) the first Englishman of mark out of parliament to attach himself openly to the new republic was John Milton. This he did by the publication of his pamphlet entitled "Tenure of Kings and Magistrates, proving that it is lawful, and hath been held so in all ages, for any one to have the power, to call to account a Tyrant or wicked King, and, after due conviction thereof, to put him to death, if the ordinary Magistrate have neglected or failed". It was out within a fortnight after the king's death, and was Milton's last performance in the house in High Holborn. The chiefs of the new republic could not but perceive the importance of securing the services of a distinguished man who had so opportunely and so powerfully spoken out in favour of their tremendous act. In March 1649, accordingly, Milton was offered, and accepted, the secretariatship for foreign tongues to the council of state of the new Commonwealth. The salary was to be £388 a year (worth about £1000 a year now). To be near his new duties in attendance on the council, which held its daily sittings for the first few weeks in Derby House, close to Whitehall, but afterwards regularly in Whitehall itself, he removed at once to temporary lodgings at Charing Cross. In the very first meetings of council which Milton attended he must have made personal acquaintance with PresidentBradshaw, Fairfax, Cromwell himself, Sir Henry Vane, White洛克,
Henry Marten, Haselrig, Sir Gilbert Pickering and the other chiefs of the council and the Commonwealth, if indeed he had not known some of them before. After a little while, for his greater convenience, official apartments were assigned him in Whitehall itself.

At the date of Milton's appointment to the secretariery, he was forty years of age. His special duty was the drafting in Latin of letters sent by the council of state, or sometimes by the Rump Parliament, to foreign states and princes, with the examination and translation of letters in reply, and with personal conferences, when necessary, with the agents of foreign powers in London, and with envoys and ambassadors. As Latin was the language employed in the written diplomatic documents, his post came to be known indifferently as the secretariery for foreign tongues or the Latin secretariery. In that post, however, his duties, more particularly at first, were very light in comparison with those of his official colleague, Walter Frost, the general secretary. Foreign powers held aloof from the English republic as much as they could; and, while Frost had to be present in every meeting of the council, keeping the minutes, and conducting all the general correspondence, Milton's presence was required only when some piece of foreign business turned up. Hence, from the first, his employment in the drafting of the council's work. Especially, the council looked to him for everything in the nature of literary vigilance and literary help in the interests of the struggling Commonwealth. He was employed in the examination of suspected papers, and in interviews with their authors and printers; and he executed several great literary commissions expressly entrusted to him by the council.

The first of these was his pamphlet entitled Observations on the Articles of Peace (between Ormonde and the Irish). It was published in May 1649, and was in defence of the republic against a complication of Royalist intrigues and dangers in Ireland. A passage of remarkable interest in it is one of eloquent eulogy on Cromwell. More important still was the Eikonoklastes (which may be translated "Imagery Smasher"), published by Milton in October 1649, by way of counterblast to the famous Eikon Basilike ("Royal Image"), which had been in circulation in thousands of copies since the king's death, and had become a kind of Bible in all Royalist households, on the supposition that it had been written by the royal martyr himself (see Auden, John). In the end of 1649 there appeared, under the title of miscellanea regis pro Carlo I, a Latin vindication of the memory of Charles, with an attack on the English Commonwealth. As it had been written, at the instance of the exiled royal family, by Salmisius, or Claude de Saumaise, of Leiden, then of enormous celebrity over Europe as the greatest scholar of his age, it was regarded as a serious blow to the infant Commonwealth. Milton threw his whole strength into a reply through the year 1650, interrupting himself only by a new and enlarged edition of his Eikonoklastes. His Latin Pro populo anglicano defensio (1651), ran at once over the British Islands and the Continent, and was received by scholars as an annihilation of Salmisius. Through the rest of 1651 the observation was that the two agencies which had co-operated most visibly in raising the reputation of the Commonwealth abroad were Milton's books and Cromwell's battles.

Through the eventful year 1651, in addition to the other duties of his secretariery, Milton acted as licensor and superintending editor of the Mercurius politicus, a newspaper issued twice a week, of which Marchamont Nedham was the working editor and chief contributor. Milton's hand is discernable in some of the leading articles.

About the end of 1651 Milton left his official rooms in Whitehall for a "garden house," he had taken on the edge of St. James's Park in what was then called Petty France, Westminster, but is now York Street. The house, afterwards 19 York Street, was occupied by James Mill and William Hazlitt in succession, and was not pulled down until 1877. Milton had now more to do in the special work of his office, in consequence of the increase of correspondence with foreign powers. But he had for some time been in allying health; and a dimness of eyesight which had been growing upon him gradually for ten years had been settling rapidly, since his labour over the answer to Salmisius, into total blindness. Before or about May 1652, when he was but in his forty-fourth year, his blindness became total, and he could go about only with some one to lead him. Hence a rearrangement of his secretariery duties. Such of these duties as he could perform at home, or by occasional visits to the Council Office near, he continued to perform; but much of the routine work was done for him by an assistant, a well-known German, George Rudolph Weckerlin, succeeded later by Philip Meadows and, eventually, by Andrew Marvell. Precisely to this time of a lull in Milton's secretariery on account of his ill-health and blindness we have to refer his two great companion sonnets "To the Lord General Cromwell" and "To Sir Henry Vane the Younger."

In 1652 died his only son, who had been born at Whitehall in the March of the preceding year. His wife died in 1653, just after she had given birth to his third daughter, Deborah. With the three children thus left him—Anne, but six years old, Mary, not four, and the infant Deborah—the blind widower lived on in his house in Pettie France in such desolation as can be imagined.

He had recovered sufficiently to resume his secretariery duties; and the total number of his dictated state letters for the single year 1652 is equal to that of all the state letters of his preceding year, the secretariery put together. To the same year there belong also three pamphlets. In November 1652 there was published Joannis Philippip Anglii responsio ad apologistam anony mni cujusdam tenebrionis, being a reply by Milton's younger nephew, John Phillips, but touched up by Milton himself, to one of several pamphlets that had appeared against Milton for his slaughter of Salmisius.

In December 1653 Cromwell's formal sovereignty began under the name of the Protectorate, passing gradually into more than kingship. This change from Government by the Rump and its council to government by a single military lord protector and his council was regarded by many as treason to the republican cause, and divided those who had hitherto been the united Commonwealth's men into the "Pure Republicans," represented by such men as Bradshaw and Vane, and the "Oliverians," adhering to the Protector. Milton, whose boundless admiration of Cromwell had shown itself already in his Irish tract of 1649 and in his recent sonnet, was recognized as one of the Oliverians. He remained in Oliver's service and was his Latin secretary through the whole of the Protectorate. For a while, indeed, some of the pamphlets that were written by Milton and Cromwell's name, or were but few—Thurloe, as general secretary, and officials of Oliver's hand-man in everything, with a Philip Meadows under him, at a salary of £500 a year, as deputy for the blind Milton in foreign correspondence and translations. The reason for this temporary exemption of Milton from routine duty may have been that he was then engaged on an answer to the pamphlet from the Hague entitled Regii sanguinis clamor ad coelum adversus parricidas anglicanos (March 1652). Salmisius was now dead, and the Commonwealth was too stable to suffer from such attacks; but no Royalist pamphlet had appeared so able or so venomous as this in continuation of the Salmisian controversy. All the rather because it was in the main a libel on Milton himself did a reply from his pen seem necessary. It came out in May 1654, with the title Joannis Miltoni Angli pro populo anglicano defensio secunda (Second Defence of John Milton, Englishman, for the People of England). The author of Regii sanguinis clamor was Dr Peter du Moulin the younger, a naturalized French Presbyterian minister, then moving about in English society, close to Milton; while the pamphlet was anonymously attributed to the Continent to an office of Morus, a Frenchman of Scottish descent then a professor at Middelburg, who had certainly managed the printing in consultation with the now deceased Salmisius, and had contributed some portion of the matter—Milton made More the responsible person and the one object of his invective. The savage attack on More's personal character, however, is but part of the Defensio secunda. It contains passages of singular autobiographical and historical value, and includes laudatory sketches of such eminent
of his generation, or of many generations; and he regarded Cromwell's assumption of the supreme power, and his retention of that power with a sovereign title, as no real suppression of the republic, but as absolutely necessary for the preservation of the republic, and for the safeguard of the British Islands against a return of the Stuarts. Nevertheless, under this prodigious admiration of Cromwell, there were political doubts and reserves. Milton was so much of a modern radical of the extreme school in his own political views and sympathies that he cannot but have been vexed by the growing conservatism of Cromwell's policy through his Protectorate. To his grand panegyric on Oliver in the Defensio secunda of 1654 he had ventured to append cautions against self-will, over-legislation and over-policing; and he cannot have thought that Oliver had been immaculate in these respects through the four subsequent years. The attempt to revive an aristocracy and a House of Lords, on which Cromwell was latterly bent, cannot have been to Milton's taste. Above all, Milton dissented in toto from Cromwell's church policy. It was Milton's fixed idea, almost his deepest idea, that there should be no such thing as an Established Church, or state-paid clergy, of any sort or denomination. The mixture of denominations, in any nation, and that, as it had been the custom in the connexion of state and church, begun by Constantine, that had vitiolated Christianity in the world, and kept it vitiated, so Christianity would never flourish as it ought till there had been universal disestablishment and disendowment of the clergy, and the propagation of the gospel were left to the zeal of voluntary pastors, self-supported, or supported modestly by their flocks. He had at one time looked to Cromwell as the likeliest man to carry this great revolution in England. But Cromwell, after much meditation on the subject in 1652 and 1653, had come to the opposite conclusion. The conservation of the Established Church of England, in the form of a broad union of all evangelical denominations of Christians, whether Presbyterians, or Independents, or Baptists, or moderate Old Anglicans, that would accept state-pay with state-control, had been the fundamental notion of his Protectorate, persevered in to the end. This must have been Milton's deepest disappointment with Cromwell's rule.

Cromwell's death on the 3rd of September 1658 left the Protectorate to his son Richard. Milton and Marvell continued in their poetical compositions, and a number of the Foreign Office letters of the new Protectorate were of Milton's composition. In October 1658 appeared a new edition of his Defensio prima, and, early in 1659, a new English pamphlet, entitled Treatise of Civil Power in Ecclesiastical Causes showing that it is not lawful to compel in Matters of Religion, in which he advocated the separation of Church and State. To Richard's Protectorate also belongs one of Milton's Latin "Familiar Epistles."

The last of his known official performances in his Latin secretariaryship are two letters in the name of William Lenthall, as the speaker of the restored Rump, one to the king of Sweden and one to the king of Denmark, both dated the 15th of May 1659. Under the restored Rump, if ever, he seemed to have a chance for his notion of church-disestablishment; and accordingly, in August 1659, he put forth, with a prefatory address to that body, a pamphlet entitled Considerations touching the likeliest means to remove Hurdings out of the Church. There was no time to attend to such matters. They were in struggle for their own existence with the army chiefs; and to prevent the restoration of the monarchy, to argue against it and fight against it to the last, was the work to which Milton set himself; the preservation of the republic in any form, and by any compromise of differences within itself, had become one thought, and the study of practical means to this end his most anxious occupation. In a Letter to a Friend concerning the Ruptures of the Commonwealth, written in October 1659, he had propounded a scheme of a kind of dual government for reconciling the army chiefs with the Rump; through the following winter, marked only by two of his Latin "Familiar Epistles," his anxiety over the signs of the growing enthusiasm throughout the country for the recall of Charles II. had risen to a passionate vehemence which found vent in a pamphlet entitled The Ready and Easy Way to Establish
MILTON

a Free Commonwealth, and the Excellence thereof compared with the Inconveniences and Dangers of readmitting Kingship to this Nation. An abridgment of this pamphlet was addressed by him to General Monk in a letter entitled "The Present Means and Brief Delineation of a Free Commonwealth" (March 1660).

Milton's proposal was that the central governing apparatus of the British Islands for the future should consist of one indis- soluble grand council or parliament, which should include all the political chiefs, while there should be a large number of provincial councils or assemblies sitting in the great towns for the management of local and county affairs.

Not even when the king's cause was practically assured would Milton be silent. In Brief Notes upon a late Sermon, published in April 1660, in reply to a Royalist discourse by a Dr Matthew Griffith, he made another protest against the recall of the Stuarts, even hinting that it would be better that Monk should become king himself; and in the same month he sent forth a second edition of his Ready and Easy Way, more frantically earnest than even the first, and containing additional passages of the most violent denunciation of the royal family, and of prophecy of the degradation and disaster they would bring back with them. This was the dying effort. On the 24th of April the Convention Parliament met; on the 1st of May they resolved unanimously that the government by King, Lords and Commons should be restored; and on the 29th of May, Charles II. made his triumphal entry into London. The chief republicans had by that time scattered themselves, and Milton was hiding in an obscure part of the city.

How Milton escaped the scaffold at the Restoration is a mystery now, and was a mystery at the time. The Commons voted that he should be taken into custody by the serjeant-at-arms, for prosecution by the attorney-general on account of his Eikonoklastes and Defensio præm, and that all copies of those books should be called in and burnt by the hangman. There was a story that Milton had once protected Davenant and now owed his immunity to him; but it is more likely that he was protected by the influence of Marvell, by Arthur Annesley, afterwards earl of Anglesey, and by other friends who had influence at court. At all events, on the 29th of August 1660, when the Indemnity Bill did come out complete, with the king's assent, Milton did not appear as one of the exceptions on any ground or in any of the grades. From that moment, therefore, he could emerge from his hiding, and go about as a free man. Not that he was yet absolutely safe. There were several public burnings by the hangman at the same time of Milton's condemned pamphlets; and the appearance of the blind man himself in the streets, though he was legally free, would have caused him to be mobbed and assaulted. Though the special prosecution ordered against him by the Commons had been quashed by the subsequent Indemnity Bill, the serjeant-at-arms had taken him into custody. Entries in the Commons journals of the 17th and 19th of December show that Milton complained of the exorbitant fees charged by the serjeant-at-arms for his release, and that the matter was referred to a committee at the instance of Andrew Marvell.

Milton did not return to Petty France. For the first months after he was free he lived as closely as possible in a house near what is now Red Lion Square, Holborn. Thence he removed, apparently early in 1661, to a house in Jewin Street, in his old Aldersgate Street and Barbican neighbourhood. In Jewin Street Milton remained for two or three years, or from 1661 to 1664. This is the time of which he says:—

"... though fallen on evil days,
On evil days though fallen, and evil tongues.
In darkness, and with dangers compassed round,
And solitude."

The "evil days" were those of the Restoration in its first or Clarendonian stage, with its reactions and reactions, its return to high Episcopacy and suppression of every form of dissent and sectarianism, its new and shameless royal court, its open proclamation and practice of anti-Puritanism in morals and in literature no less than in politics. For the main part of this world of the Restoration Milton was now nothing more than an infamous outcast, the detestable blind republican and regicide who had, by too great clemency, been left unhanged. The friends that adhered to him still, and came to see him in Jewin Street, were few in number, and chiefly from the ranks of those nonconformist denominations, Independents, Baptists or Quakers, who were themselves under similar obloquy. Besides his two nephews, the faithful Andrew Marvell, Cyliaek Skinner and some others of his former admirers, English or foreign, we hear chiefly of a Dr Nathan Paget, who was a physician in the Jewin Street neighbourhood, and of several young men who would drop in upon him by turns, partly to act as his amanuenses, and partly for the benefit of lessons from him—one of them a Quaker youth, named Thomas Ellwood. With all this genuine attachment to him of a select few, Milton could truly enough describe his condition after the Restoration as one of "solitude." Nor was this the worst. His three daughters, on whom he ought now to have been able principally to depend, were his most serious domestic trouble. The poor motherless girls, the eldest in her seventeenth year in 1662, the second in her fifteenth and the youngest in her thirteenth year, had grown up, in their father's blindness and too great self-absorption, ill-looking and uneducated; and the result now appeared. They "made nothing of neglecting him"; they rebelled against the drudgery of reading to him or otherwise attending on him; they "did combine together and counsel his maid-servant to cheat him in her marketings"; they actually "had made away some of his books, and would have sold the rest."

It was to remedy this state of things that Milton consented to a third marriage. The wife found for him was Elizabeth Minshull, of a good Cheshire family, and a relative of Dr Paget. They were married on the 24th of February 1662/3, the wife being then only in her twenty-fifth year, while Milton was in his fifty-fifth. She proved an excellent wife; and the Jewin Street household, though the daughters remained in it, must have been under better management from the time of her entry into it. Meanwhile, he had found some solace in a renewed industry of various kinds among his books and tasks of scholarship, and more particularly he had been building up his Paradise Lost. He had begun the poem in earnest, we are told, in 1658 at his house in Petty France, not in the dramatic form contemplated eighteen years before, but deliberately in the epic form. He had made but little way when there came the interruption of the anarchy preceding the Restoration and of the Restoration itself; but the work had been resumed in Jewin Street and prosecuted there steadily, by dictations of twenty or thirty lines at a time to whatever friendly or hired amanuensis chance to be at hand. Considerable progress had been made in this way before his third marriage; and after that the work proceeded apace, his nephew, Edward Phillips, who was then out in the world on his own account, looking in when he could to revise the growing manuscript.

It was not in the house in Jewin Street, however, that Paradise Lost was finished. Not very long after the third marriage, probably in 1664, he removed to another house, with a garden, in "Artillery Walk, leading to Bunhill Fields." Here Paradise Lost was certainly finished before July 1666—Aubrey says in 1663—for when Milton and his family, to avoid the Great Fire, had gone into temporary country quarters in a cottage in Chalfont St Giles, Buckinghamshire,1 the finished manuscript was taken with him, in probably more than one copy. This we learn from Thomas Ellwood, who had taken the cottage for him, and was allowed to take a copy of the manuscript with him for perusal, during Milton's stay at Chal- font (Life of Thomas Ellwood, 1714). The delay in the publica- tion of the poem may be explained partly by the fact that the official licenser hesitated before granting the necessary imprima- tur to a book by a man of such notorious republican antecedents, and partly by the paralysis of all business in London by the Great Fire of September 1666. It was not till the 27th of April 1667 that Milton concluded an agreement, still preserved in the British

1 Milton's cottage here is still standing, and is open to visitors.
MILTON

Museum, with Samuel Simmons, printer, of Aldersgate Street, London, to dispose of the copyright for £5 down, the promise of another quarter's pay and half of the first edition of 1,500 copies, and the further promise of two additional sums of 5s each after the sale of two more editions of the same size respectively. It was as if an author now were to part with all his rights in a volume for £57, 10s. down, and a contingency of £52, 10s. more in three equal instalments. The poem was duly entered by Simmons as ready for publication in the Stationers' Registers on the 20th of the following August; and shortly after that date it was out in London as a neatly printed small quarto, with the title Paradise Lost: A Poem written in Ten Books: By John Milton. The reception accorded to Paradise Lost has been quoted as an example of the neglect of a great work, but the sale of an edition of 1,300 copies in eighteen months proves that the poem found a wide circle of readers. "This man cuts us all out, and the ancients too" is the saying attributed to Dryden on the occasion; and it is the more remarkable because the one objection to the poem which at first, we are told, "stumbled many" must have "stumbled" Dryden most of all. Except in the drama, rhyme was then thought essential to prolonging a poem; but very gradually regarded as given at all; Dryden especially had been and was the champion of rhyme, contending for it even in the drama. That, notwithstanding this obvious blow struck by the poet at Dryden's pet literary theory, he should have welcomed the poem so enthusiastically and proclaimed its merits so emphatically, says much of course for his critical perception and for the generosity of his temper. According to Aubrey, Dryden requested Milton's leave to turn the poem into a rhymed drama, and was told he might "tag his verses if he pleased." The result is seen in Dryden's opera, The State of Innocence and the Fall of Man (1675). One consequence of Milton's renewed celebrity was that visitors of all ranks again sought him out for the honour of his society and conversation. His obscure house in Artillery Walk, Bunhill, we are told, became an attraction now, "much more than he did desire," for the learned notabilities of his time.

Accounts have come down to us of Milton's personal appearance and habits in his later life. They describe him as to be seen walking in the streets in the vicinity of his Bunhill residence, a slender figure, of middle stature or a little less, generally dressed in a grey coat or overcoat, and wearing sometimes a small silver-hilted sword, evidently in feeble health, but still looking young. It is said of him that his figure, his height, his light, his aged or pale, complex. He would sit in the garden at the door of his house, in warm weather, in the same kind of grey overcoat, and so, as well as in his room, the received visits of people of distinction and curiosity. In his dressing he was "the fashion," and his doublet and hose, and stockings and shoes, and the pompadour, and his painted hair, and his bandboxes, and his gloves and his powder, and his embroidered coat. He was a very early riser, and very regular in the distribution of his day, spending the first part, to the midday dinner, always in his own room, amid his books, with an amanuensis to read to him. In the evening he usually retired to bed, after a free conversation, either at the midday dinner, when a friend or two happened, by rare accident, to be present, or more habitually in the evening and in the light supper which concluded it, he was the life and soul of the company, from his "amiable looks and eloquence, with a severity in his manner, and a marked tendency to the satirical and sarcastic in his criticisms of men and things. This tendency to the sarcastic was connected by some of those who observed it with a peculiarity of his way of dressing." He was described as "writing his manuscript in slender type, and smoking his pipe and drinking a glass of water, and went to bed." He suffered much from gout, the effects of which had become apparent in a stiffening of his hands and finger-joints, and the recurring attacks of which in its acute form were very painful. His favourite poets were the ancient and Horace, and his favourite tragedians, Euripides; among the Latins, Virgil and Ovid; among the English, Spenser and Shakespeare. Among his English contemporaries, he thought most highly of Cowley. He had ceased to attend any church, belonged to no religious community, and had no religious observances in his family. His reasons for this were a matter for curious surmise among his friends, because of the profoundly religious character of his own mind; but he does not seem ever to have published the explanation. The matter became of less interest perhaps after 1669, when his three daughters ceased to reside with him, having been sent out "to learn some curious and ingenious sorts of manufacture that are proper for women to learn, particularly embroidery in gold or silver." After that the household in Bunhill consisted only of Milton, his wife, a single maid-servant, and the "man" or amanuensis who came in for the day.

The remaining years of Milton's life, extending through that part of the reign of Charles II, which figures in English history under the name of the "Calab Administration," were by no means unproductive. In 1669 he published, under the title of Accedence commenced Grammar, a small English compendium of Latin grammar that had been lying among his papers. In 1670 there appeared, with a prefixed portrait of him by Faithorne, done from the life, His History of Britain... to the Norman Conquest, being all that he had been able to accomplish of his intended complete history of England; and in the same year a Latin digest of Ramist logic, entitled Aris logicae plenior institute, of no great value, and doubtless from an old manuscript of his earlier days. In 1671 there followed his Paradise Regained and Samson Agonistes, bound together in one small volume, and long ample praise that his poetic genius had not exhausted itself in the preceding great effort. In 1673, at a moment when the growing political discontent with the government of Charles II. and the conduct of his court had burst forth in the special form of a "No-Popery" agitation and outcry, Milton ventured on the dangerous experiment of one more political pamphlet, in which, under the title "Of True Religion, Heresy, Schism, Toleration, and what best may be used against the growth of Popery," he put forth, with a view to popular acceptance, as mild a version as possible of his former principles on the topics discussed. In the same year appeared the second edition of his Poems... both English and Latin, which included, with the exception of the Sonnets to Cromwell, Fairfax, Vane and the second address to Cyriack Skinner, all the minor poems.

Thus we reach the year 1674, the last of Milton's life. One incident of that year was the publication of the second edition of Paradise Lost, with the poem rearranged as now—into twelve books, instead of the original ten. Another was the publication of a small volume containing his Latin Epistolae familiares, together with the Prolocutoria oratoria of his student-days at Cambridge—these last thrown in as a substitute for his Latin state-letters in his secretaryship for the Commonwealth and the Protectorate, the printing of which was stopped by order from the Foreign Office. A third publication of the same year, and probably the very last thing dictated by Milton, was a translation of a Latin document from Poland, relating to the recent election of the heroic John Sobieski to the throne of that kingdom, with the title A Declaration or Letters Patents of the Election of this Present King of Poland, John the Third. It seems to have been out in London in August or September 1674. On Sunday the 8th of the following November Milton died, in his house in Bunhill, of "gout struck in," at the age of sixty-five years and eleven months. He was buried, the next Thursday, in the church of St Giles, Cripplegate, beside his father; a considerable concourse attending the funeral.

Before the Restoration, Milton—what with his inheritance from his father, what with the official income of his Latin secretaryship—must have been a man of very good means indeed. Since then, however, various heavy losses, and the cessation of all official income, had greatly reduced his estate, so that he left but £500 (worth about or over £2700 now) besides furniture and household goods. By a word-of-mouth will, made in presence of his brother Christopher, he had bequeathed the whole to his widow, on the condition that he had done enough already for his "undutiful" daughters, and that there remained for them his interest in their mother's marriage portion of £1000, which had never been paid, but which their relatives, the Powells of Forest Hill, were legally bound for, and were now in possession of.
circumstances to make good. The daughters, with the Powells probably bettng them, went to law with the widow to upset the will; and the decision of the court was that they should receive £100 each. Later, in 1680, she left, the widow, after some further stay in London, retired to Nantwich in her native Cheshire. There, respected as a pious member of a local Baptist congregation, she lived till 1727, having survived her husband fifty-three years. By that time all the three daughters were also dead. The eldest, Ann Milton, who was somewhat deformed, had died not long after her father, having married “a master-builder,” but left no issue; the second, Mary Milton, had died, unmarried, before 1694; and only the third, Deborah, survived as long as her step-mother. Having gone to Ireland, as companion to a lady, shortly before her father’s death, she had married an Abraham Clarke, a silk-weaver in Dublin, with whom she returned to London about 1684, when they settled in the silk-weaving business in Spitalfields, rather sinking than rising in the world, though latterly some public attention was paid to Deborah, by Addison and others, on her father’s account. One of her sisters, Caleb Clarke, had gone out to Madras in 1703, and had died there as “parish-clip of Fort George” in 1719, leaving children, of whom there are some slight traces to as late as 1727, the year Deborah died. Except for the possibility of a slight untraced descent from this Indian grandson of Milton, the direct descent from him came to an end in his grandson, Elizabeth Clarke, another of Deborah’s children. Having married a Thomas Foster, a Spitalfields weaver, but afterwards set up a small chandler’s shop, first in Holloway and then in Shoreditch, she died at Islington in 1754, not long after she and her husband had received the proceeds of a performance of Comus got up by Dr Johnson for her benefit. All her children had predeceased her, leaving no issue. Milton’s brother Christopher, who had always been on the opposite side in politics, rose to the questionable honour of a judgeship and knighthood in the latter part of the reign of James II. He had then become a Roman Catholic—which religion he professed till his death in retirement at Ipswich in 1692. Descendants from him are traceable a good way into the 18th century. Milton’s two nephews and pupils, Edward and John Phillips, both of them known as busy and clever hack-authors before their uncle’s death, continued the character of scholar, most industriously to the very last, though not very prosperously, through the rest of their lives: Edward in a more reputable manner than John, and with more of enduring allegiance to the memory of his uncle. Edward died about 1695; John was alive till 1706. Their half-sister, Ann Agar, the only daughter of Milton’s sister by her second husband, had married, in 1673, a David Moore, of Sayes House, Chertsey; and the most flourishing of all the lines of descent from the poet’s father was in this Agar-Moore branch of the Miltons.

Of masses of manuscript that had been left by Milton, some portions saw the light posthumously. Prevented, in the last year of his life from publishing his Latin State Letters in the same volume with his Latin Poems and Historical Publications—committed the charge of the State Letters, prepared for the press, together with the completed manuscript of his Latin Treatise of Christian Doctrines, to a young Cambridge scholar, Dominic Elzevir, who had been among the last of his amanuenses, and had, in fact, been employed by him especially in copying out and arranging those two important MSS. Negotiations were on foot, after Milton’s death, between this Daniel Skinner and the Amsterdam printer, Daniel Elzevir, John to whom, it is said, the whole of the MSS. were sent back by Elzevir, and thrown aside, as dangerous rubbish, in a cupboard in the State Paper Office. Meanwhile, in 1676, a London bookseller, named Pitt, who had some reputation as a less than complete, copy of the State Letters, had brought out a surreptitious edition of them, under the title Literae pseudo-seiatus Anglicae, Cromwellis . . . nomine et jussu conscriptae ad Joanne Miltono. No other posthumous publications of Milton appeared till 1682, when another bookseller, Edward Sponne, a slight tract entitled Mr John Milton’s Character of the Long Parliament and Assembly of Divines, in 1641, consisting of a page or two, of rather dubious authenticity, said to have been withheld from his History of Britain in the edition of 1670. In 1682 appeared A Brief History of Moscova, and of other less-known Countries lying Eastward of Russia as far as Cathay . . . undoubtedly Milton’s, and a specimen of those prose compilations with which he sometimes occupied his leisure. Of the fate of his collections for a new Latin Dictionary, which had swelled to three folio volumes of MS., all that is known is that, after having been used by Edward Phillips for his En chiridion, and Speculum, they came into the hands of a committee of Cambridge scholars, and were used for that Latin dictionary of 1656, The Cambridge Dictionary, on which Ainsworth’s Dictionary was based. In 1686 there was published in three folio volumes, under the title of The Life of John Milton, a fine collection of Milton’s prose works, professing to have been printed at Amsterdam, of which the only really printed in London. A very interesting folio volume, published in 1743 by “John Nickollis, junior,” under the title of Original Letters and Papers of State addressed to Oliver Cromwell, consists of a number of dated State Cromwellian documents that somehow came into Milton’s possession immediately after Cromwell’s death, and were left by him confidentially to the Quaker Ellwood. Finally, a chance search in the London State Paper Office in 1823 having discovered the lost long-past pared containing the MSS. of Milton’s Latin State Letters and his Latin Treatise of Christian Doctrine, as these had been sent back from Amsterdam a hundred and fifty years before, the Treatise on Christian Doctrine was, by the command of George IV., and published in 1825 by the Rev. C. R. Summer, keeper of the Royal Library, and afterwards bishop of Winchester, under the title of Joannis Miltoni Angli de doctrina christiana libri duo posthumi. An English translation, by the editor, was published in 1831, The text was again printed in 1835 by the Rev. C. B. R. Summer, keeper of the Royal Library, and afterwards bishop of Winchester, and the volume is now in the Cambridge Library.

Milton’s literary life divides into three almost mechanically distinct periods: (1) the time of his youth and minor poems, (2) his middle twenty years of prose polemics, and (3) the time of his later Muse and greater poems.

Had Milton died in 1640, when he was in his thirty-second year, and had his literary remains been then collected, he would have been remembered as one of the best Latins of his generation and one of the most exquisite of minor English poets. In the latter character, more particularly, he would have taken his place as one of that interesting group or series of English poets, coming in the next forty years after Spenser, who, because they all acknowledged a filial relationship to Spenser, may be called collectively the Spenserians. In this group or series, counting in it such other true poets of the reigns of James I. and Charles I. as Phineas and Giles Fletcher, William Browne and Drummond of Hawthornden, Milton would have been entitled, by the small collection of pieces he had left, and which would have included his Ode on the Nativity, his L’Alegro and II Penseroso, his Comus and his Lycidas, to recognition as indubitably the very highest and finest. There was in him that peculiar Spenserian something which might be regarded as the poetic faculty in its essence, with a closeness and perfection of verbal finish not to be found in the other Spenserians, or even in the master himself. Few as the pieces were, and owning discipleship to Spenser as the author did, he was a Spenserian with a difference belonging to his own constitution—which prophesied, and indeed already exhibited, the passage of English poetry out of the Spenserian into a kind that might be called the Miltonic. This Miltonic something, distinguishing the new poet from other Spenserians, was more than mere perfection of literary finish. It consisted in an avowed consciousness already of the os magna sonoratum, “the mouth formed for great utterances,” that consciousness resting on a peculiar substratum of personal character that had been disciplined by a moral theory of life. “If a man be not to be frustrated of his hope, to work well hereafter on laudable things ought himself to be a true poet,” was Milton’s own memorable expression afterwards of the principle that had taken possession of him from his earliest days; and this principle of moral manliness as the true foundation of high literary effort, of the inexpressible identity of all literary productions in kind, and their coevality in worth, with the personality in which they have their origin, might have been detected, in more or less definite shape, in all or most of the minor poems. It is a specific form of that general Platonic doctrine of the invincibility of virtue which runs through his Comus.

That a youth and early manhood of such poetical promise should have been succeeded by twenty years of all but incessant prose polemics has been a matter of regret with many. But this
is to ignore his political and social side. If Burke, whose whole public career consisted in a succession of speeches and pamphlets, is looked back upon as one of the greatest men of his century on their account, we should therefore regret over the fact that Milton, after having been the author of Comus and Lycidas, became for a time the prose orator of his earlier and more tumultuous generation? Milton was not only the greatest pamphleteer of his generation—head and shoulders above the rest—but there is no life of that time, not even Cromwell's, in which the history of the great Revolution in its successive phases, so far as the deep underlying ideas and speculations were concerned, may be more intimately and instructively studied than in Milton's. Then, on merely literary grounds, what an interest in those prose remains! Not only of his Areopagitica, admired now so unreservedly because its main doctrine has become axiomatic, but of most of his other pamphlets, even those the doctrine of which is least popular, it may be said confidently that they answer to his own definition of "a good book," by containing somehow "the precious life-blood of a master spirit." From the entire series there might be a collection of speeches and pamphlets nowhere, the capabilities of that older, grander and more elaborate English prose of which the Elizabethans and their immediate successors were not ashamed. Nor will readers of Milton's pamphlets continue to accept the hackneyed observation that his genius was destitute of humour. Though his prevailing mood was the severely earnest, there are pages in his prose writings, both English and Latin, of the most laughable irony, reaching sometimes to outrageous farce, and some of them as worthy of the name of humour as anything in Swift. Here, however, we touch on what is the worst feature in some of the prose pamphlets—their measureless ferocity, their boundless licence in personal scurrility.

While it is wrong to regard Milton's middle twenty years of prose polemics as a degradation of his genius, and while the fairer contention might be that the youthful poet of Comus and Lycidas actually promoted himself, and became a more powerful agency in the world and a more interesting object in it for ever, by consenting to lay aside his "singing robes" and spend a portion of his life in great prose oratory, who does not exult in the fact that such a life was rounded off so miraculously at the close by a final stage of compulsory calm, when the "singing robes" could be resumed, and Paradise Lost, Paradise Regained and Samson Agonistes could issue in succession from the blind man's chamber? Of these three poems, and what they reveal of Milton, no need here to speak at length. Paradise Lost is one of the few monumental works of the world, with nothing in modern epic literature comparable to it except the great poem of Dante. This is best perceived by those who penetrate beneath the beauties of the merely terrestrial portion of the story, and who recognize the coherence and the splendour of that vast symbolic phantasmagory by which, through the wars in heaven and the subsequent revenge of the expelled archangel, it paints forth the connexion of the whole visible universe of human cognisance and history with the grander, pre-existing and inconceivable. To this great epic Paradise Regained is a sequel, and it ought to be read as such. The legend that Milton preferred the shorter epic to the larger is quite incorrect. All that is authentic on the subject is the statement by Edward Phillips that, when it was reported to his uncle that the shorter epic was "generally censured to be much inferior to the other," he "could not hear with patience any such thing." The best critical judgment now confirms Milton's own, and pronounces Paradise Regained to be not only, within the possibilities of its briefer theme, a worthy sequel to Paradise Lost, but also one of the most artistically perfect poems in any language. Finally, the poem in which Milton bade farewell to the Muse, and in which he reverted to the dramatic form, proves that to the very end his right hand had lost none of its power or cunning. Samson Agonistes is the most powerful drama in the English language after the severe Greek model, and it has the additional interest of being so contrived that, without any penalties from the strictly objective incidents of the Biblical story which it enshrines, it is yet the poet's own epitaph and his condensed autobiography.

Much light is thrown upon Milton's mind in his later life, and even upon the poems of that period, by his posthumous Latin Treatise of Christian Doctrine. It differs from all his other prose writings of any importance in being cool, abstract and didactic. Professing to be a system of divinity derived directly from the Bible, it is really an exposition of Milton's metaphysics and of his reasoned opinions on all questions of philosophy, ethics and politics. The general effect is to show that, though he is rightly regarded as the very genius of English Puritanism, its representative poet and idealist, yet he was not a Puritan of what may be called the first wave, or that wave of Calvinistic orthodoxy which broke in upon the absolutism of Charles and Laud, and set the English Revolution a-going. He belonged distinctly to that larger and more persistent wave of Puritanism which, passing on through Independency, and an endless variety of sects, many of them rationalistic and freethinking in the extreme, evolved out of what has ever since been known as English Liberalism. The treatise makes clear that, while Milton was a most fervid theist and a genuine Christian, believing in the Bible, and valuing the Bible under all the other books in the world, he was at the same time one of the most intrepid of English thinkers and theologians.

Considerable interest attaches among collectors to the variety of prints representing portraits of Milton. So far as the original contemporary portraits are concerned, which have inspired the large number of engravings, the following may be mentioned: (1) "The existing Janssen painting, 1618 ("aetat. suea 10"), which belonged to Mrs Milton. (2) An unknown painting of 1623 (?1620), from which was taken an engraving in the Gentleman's Magazine for September 1787 ("aet. suea 12"). (3) The "Onslow" painting of Milton when a Cambridge scholar (lost), which belonged to Mrs Milton and in 1794 was in Lord Onslow's possession; a copy by Van der Gucht was made for Lord Harcourt and is now at Nuneham. (4) William Marshall's engraved frontispiece to Moseley's edition of the poems (1645). (5) William Faithorne's engraving of Milton from life, at the age of sixty-two, in Milton's History of Britain (1760). (6) Faithorne's original drawing for the above, belonging in 1900 to Sir R. H. Hobart. (7) The Bayfordbury (or Tonson) drawing (probably by Faithorne, or (? by White or Richardson) at Bayfordbury Park near Hertford. (8) A drawing by George Vertue in Dr Williamson's collection. (9) A clay bust (? by Pierce or Simon) at Christ's College. (10) A miniature by Cooper (1653), which is, however, considered by Dr G. C. Williamson not to be of Milton at all. (11) A painting by Pieter Van der Plas (d. 1704) in the National Portrait Gallery. (12) An oil painting at Christ's College. (13) The "Woodcock" miniature of Milton when about forty-eight. In Poets' Corner, Westminster Abbey, a bust by Rysbrack was put up in 1735. A monument in St Giles, Cripplegate, by John Bacon, R.A., was erected by Samuel Whitbread in 1793 and a modern statue by Horace Woodford also stands there. A memorial window in St Margaret's, Westminster, with an inscription by J. G. Whittier, was presented by G. W. Childs, of Philadelphia.

BIBLIOGRAPHY.—MSS. of the poems of Milton's earlier period in his own handwriting are preserved in the library of Trinity College, Cambridge. Two quarto copies of the Poetical Works are in the library of Sir Henry Newton Puckering in 1691, but presumably belonged to him, and came to the library at his death in 1700, as they were found by Charles Mason, a fellow of the college, among papers and books in his collection which had been bought by him in 1576 for the use of Thomas Clarke, afterwards Master of the Rolls, in 1736. Besides the poems, with many interlineations and corrections, the MS. contains suggestions, and in some cases fully developed passages, which are interesting in showing Milton's genius in an invaluable index to Milton's methods of work, was reproduced in facsimile (Cambridge, 1889) by W. Aldis Wright.

The first complete edition of The Poetical Works of John Milton was, printed by Jacob Tonson in 1645. In 1728 Richard Bentley put forward a curious edition of Paradise Lost in which long passages were rejected and placed in the margin on the ground that they were interpolations made possible by Milton's blindness. The Latin and Italian poems, with a translation by William Cowper,
MILTON—MILWAUKEE

were printed by W. Hayley in 1808. The most important of the numerous later editions of Milton’s poetical works are by H. J. Tod (6 vols., 1801); J. Mitford ("Aldine edition," 3 vols., 1832); T. Keightley (2 vols., 1859), whose notes are most original and interest-ing; and F. G. Wood MS. D. J. Todd (1860). The first of these, in which a new edition appeared in 1890, with memoir, introduction, notes and an essay on Milton’s English and versification; John Bradshaw (new "Aldine edition," 2 vols., 1892); a careful reprint made by Oxford University Press in 1894, with copious critical notes and Beeching ("Oxford edition," 1904); and another, with variant readings, by W. Aldis Wright (Cambridge University Press, 1905). The prose works were first partially collected in 1667. They were edited by J. Toland (vols., 1668), by C. Symonds (vols., 1860) by Pickering (8 vols., 1851) with the poetical works, and by J. A. St John for Bohn’s "Libraries" (5 vols., 1848–1853). There are numerous annotated editions of separate works.

The life of Milton is contained in Wood MS. D. 4, in the Bodleian Library, Oxford, and was written in the Eng. Hist. Review for January 1902, also by E. S. Parsons in Colorado College Studies, No. X (1903). The author, who sympathized with the poet’s political views, is unknown, but the name of Milton’s friend, Dr. Johnson, was suggested. His account forms the basis of the life given by Anthony A Wood in Fasti axonienses (1691). Wood was also indebted to John Aubrey, whose Brief Lives were not printed until later. This life by his nephew Edward Phillips was prefixed to his edition of Milton’s works published in 1705. The first complete biographical sketch was written by Godwin in Lives of E. and J. Phillips (1815). Samuel Johnson’s famous Life of Milton (1779), which contains some valuable criticism, is written from a somewhat unfriendly standpoint. The remnants of the life of Milton, and also of the Milton family, are first made use of by H. J. Tod in a third edition (1829) of his Milton. All the available information was gathered in Professor Masson’s Life of John Milton; narrated in connexion with the Political, Ecclesiastic, and Literary History of England (1821), a monumental work which contains ample reference to original authorities. Shorter works are Milton and seine Zeit (2 pts., 1877, 1879), by Alfred Stern; Milton (1879), by Mark Pattison in the "Great Writers." A History of Life, and of Life of John Milton (1890) by Dr. Richard Garnett in the "Great Writers" series, with a bibliography by J. P. Anderson.

The sources of Paradise Lost have given rise to much discussion. It was extensively discussed by J. Burnet in 1661; C. W.换句话说, by Giovanni Battista Andreini (1758–162), to the Paraphrase associated with the name of Caedmon which was printed at Amsterdam in 1655 by Francis Junius, and to the Lucifer and other plays of Joost van den Vondel. Parallels between Vondel and Milton were pointed out by Mr. Edmund Gosse in Littérature of Northern Europe (1879), and the comparison was carried further in Mr. G. Edmundson’s Milton and Vondel; A Curiosity of Literature (1885), a book which aroused much discussion. A valuable contribution to Miltonic criticism was made in 1893 by Mr. Robert Bridges in an article on Milton’s Prosody. This was reprinted in 1901, with some additional matter and an essay on "Classical Metres in English Verse," by W. J. Stoddart. Among such other essays would be mentioned M. L. Milne (Edinburgh Review, 1882); W. C. Dening (Literary Studies, vol. I., 1879; S. C. Coleridge (Seven Lectures on Shakespeare and Milton 1856); Edward Dowden (Transcripts and Studies, 1888); Edward Scherer (Editions de la littérature contemporaine, 1887). See also J. Custance Burcell (Order of Worlds, second series, 1887); Walter Raleigh (Milton, 1900); E. Alldoli, Giovanni Milton e Italia (Prato, 1907).

Concordances of Milton’s Poetical Works were compiled by G. L. Percival (1856–1857); by C. J. Cleveland (1867), based on a verbal index used in an American edition 1833, of the Poetical Works; by John Bradshaw (1894), by L. E. Lockwood, Lexicon to the English Poetical Works of John Milton (New York, 1837).

Milton was born in London in 1608. He was educated at the universities of Cambridge, London and elsewhere. An exhibition of the portraits of Milton, authentic and supposed, with a great collection of valuable editions of the poet’s works, was held in June and July at Christ’s College, Cambridge. Another exhibition was held in 1864 at the British Museum, and W. C. Dening was the principal exhibitioner. A similar exhibition was held by Dr. G. C. Williamson, forms a valuable bibliography and iconography of the poet. A collection of Milton autographs, early editions and portraits was also held in December at the British Museum, and was afterwards sold to the British Museum, by W. J. Stoddart, were read. There was a religious service at St. Mary-le-Bow, Cheapside, and a banquet at the Mansion House.

MILTON, a township of N.E. Norfolk county, Massachusetts, U.S.A., about 7 m. S. of Boston, the Neponset river forming a large part of its N. and W. boundary. Pop. (1890), 4728; (1900), 6768 (1840 being foreign-born); (1905, state census), 7054; (1910) 7924. It is served by the New York, New Haven & Hartford railroad, and is primarily a residential suburb of Boston, with which it is connected by electric lines. The township covers an area of about 13 sq. m., and includes the villages of Milton, East Milton and Mattapan. The country is rolling and hilly, the Blue Hills (with the exception of a part included in Braintree, in 1712 and now in Quincy) lying in Milton. On Great Blue Hill, the highest (493 ft. above tide-level), great fires were kindled at the news of the repeal of the Stamp Act, of the adoption of the Declaration of Independence, and of the surrender of Burgoyne and Cornwallis; beacon fires were burned during the American War of Independence; an “observatory” for tourists was built at an early date; and in 1885 the Blue Hill Observatory for meteorological investigation was established by Abbott Lawrence Rotch (b. 1851), who made important investigations concerning clouds, and attracted attention by his use of kites for obtaining meteorological data. Milton Academy (a non-sectarian school) was founded in 1798, opened in 1805, and suspended in 1867; a new academy was opened in 1885. There is a public library, which was opened in 1871, and in 1909 had more than 20,000 volumes. Cunningham Park is under the control of the trustees of a fund left for the benefit of the township, and contains a gymnasium, skating-pond, tennis courts, &c., open to townpeople only. Hutchinson Field, another public park, is part of the estate of the last royal governor, Thomas Hutchinson; Governors Island, a part of Rock Island, is in Milton for a time. There are two granite quarries in the township immediately north-west of the Blue Hills; the granite is of the “dark granite” variety—dark bluish grey in colour—and is used chiefly for monuments. Milton, originally a part of Dorchester, was first settled in 1640, and was called Uncataquisset.

The township was separated from Dorchester and incorporated in 1662. It owes its name either to its early paper and grist mills (Milton being abbreviated from Milltown) or to Milton Abbey, Dorset, whence members of the Tucker family came, it is supposed, to Milton about 1662. In 1712 the Blue Hill lands were divided between Milton and Braintree, and in 1886 part of Milton was included in the new township of Hyde Park. In Milton, on the 9th of September 1774, at the house of Daniel Vose, a meeting, adjourned from Dedham, passed the bold "Suffolk Resolves" (Milton then being included in Suffolk county), which declared that a sovereign who breaks his compact with his subjects forfeits their allegiance, that parliament’s repressive measures were unconstitutional, that tax-collectors should not pay over money to the royal treasury, that the towns should choose militia officers from the patriotic party, that they would obey the Continental Congress and that they favoured a Provincial Congress, and that they would seize crown officers as hostages for any political prisoners arrested by the governor; and recommended that all persons in the colony should abstain from lawlessness.

MILTON, a borough of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river at the mouth of Limestone Run, about 66 m. N. of Harrisburg. Pop. (1890), 5317; (1900), 6175 (166 foreign-born); (1910), 7460. It is served by the Pennsylvania, and the Philadelphia & Reading railways, and is connected by electric railways with York and Watertown by an electric line. Milton has an attractive public park, is in an agricultural region, and has various manufactures. It was founded in 1792, and incorporated as a borough in 1817. It was in great part destroyed by fire.

MILWAUKEE, a city and the county-seat of Milwaukee county, Wisconsin, U.S.A., the largest city of the state, at the mouth of the Milwaukee river on the W. shore of Lake Michigan, about 85 m. N. of Chicago. Pop. (1900), 285,315; (1910), 373,857. The Milwaukee river entering the city from the north is joined by ½ m. from its mouth by the Menominee flowing from the west and a short distance from the lake by the Kinnekinnic flowing from the south. These rivers are navigable for lake traffic into the heart of the city. Milwaukee Bay, into which their combined waters empty, is an inlet of Lake Michigan, about 6 m. across. By the construction of extensive piers and breakwaters a fine harbour of refuge has been created; and its inner harbour is deep enough for the largest lake-steamers.
MILWAUKEE

From the shore of the lake the land rises, rather abruptly in most places, to a height of from 75 to 100 ft. From a broad plateau overlooking the lake the land slopes gradually westward to the river, again rising on the north, west and south to a height of 125 ft. or more. The rivers separate the city into three distinctly marked divisions of varying character known as the east, west and south sides. The manufactories are largely on the "flats" along the rivers and on the south side. The extensive use as building material of cream-coloured brick made in the vicinity gives the city its nickname, "the Cream City."

The city has many beautiful parks and squares, the most picturesque of which is Juneau Park, along the lake bluff. It contains statues of Leif Ericsson and Solomon Juneau. Other parks are Lake Park, also on the lake shore, at North Point, where stands the waterworks pumping station with its tall tower; Riverside and Kilbourn Parks, east and west respectively of the upper Milwaukee river, in the northern part of the city, Washington Park on the west side, containing a menagerie and a herd of deer; Sherman Park on the west side, and Kosciusko, Humboldt and Mitchell Parks on the south side. McKinley Park on the lake shore south of the city, and Whitefish Bay 6 m. north of the city, are popular bathing resorts. In addition to the streets, Juneau Park there is a statue of Kosciusko in the park of that name; one of Washington and a soldier's monument on Grand Avenue; a statue of Henry Bergh in front of the city hall; one of Robert Burns in the First Ward Park, and, in Washington Park, a replica of Ernst Rietschel's Schiller-Goethe monument in Jena, given to the city in 1908 by the Germans of Milwaukee. Of the several cemeteries, that of Forest Home, south-west of the city, is the largest and most beautiful. The city is well served, and has a good electric supply system owned by the municipality and representing an investment of more than $5,000,000. The water is obtained from Lake Michigan through an intake far out in the lake. Through a tunnel 1/2 m. long, constructed in 1888, water is pumped by means of one of the largest single pumps in the world from the lake into the upper Milwaukee river, which is thus completely flushed by fresh water every twenty-four hours.

Milwaukee is one of the most healthful of the larger cities of the United States. Its average annual death-rate for 1900–1904 was 13.6. The proximity of Lake Michigan cools the atmosphere in summer and tempers the cold in winter. As a result, the extremes of heat and cold are not as great as those in most inland cities. The mean monthly temperatures vary between 20° in January and 70° in July, with extremes of 100° and −25°. The mean annual precipitation is 31.4 in.

Suburbs.—Milwaukee proper occupies 221 1/2 sq. m., a small area as compared with other cities near it in population—Detroit (36 sq. m.) and Washington, D.C. (69 1/2 sq. m.). As a result, the population has overflowed into several populous suburbs industrially a part of the city is the Federal building, Qf (1859) for the most important are the township of Wauwatosa (pop. 1905, 11,132; 1910, 11,539), and the city of the same name, separated from the township in 1897 and having in 1910 a population of 3,346; the city and township of Menasha, having an aggregate population of 12,992, was incorporated in 1907 and is the largest suburban manufacturing community, containing the town of Menasha and the villages of Oneida, Kaukauna and Grand Chute. The last-named connects with the main line at Ludington, Michigan, by means of a railway owned by the L. and M. J. Turnverein of Milwaukee, a local club of girls, and has a ferry from Milwaukee to Grand Haven. The city's extensive street railway system connects with interurban electric lines leading to Waukesha, Oconomowoc and Watertown on the west, Sheboygan and Fond du Lac on the north, and Chicago and intermediate points along the lake shore on the south.

Trade and Commerce.—Commercially Milwaukee is one of the most important of the inland cities of the United States, although its trade is largely domestic. It is a distributing point for a considerable part of the grain, rye flour and malt produced in Wisconsin. The wholesale business aggregating about $350,000,000 annually. The country produce sold in Milwaukee averages about $75,000,000 a year in value. The chief commodities of trade are coal, grain, flour and malt, the products of the city's own manufactories. Milwaukee is an important grain shipping port—in 1908 it shipped 28,618,510 bushels of grain and 3,752,033 barrels of flour, and its 25 elevators have a capacity of over 12,500,000 bushels. It is one of the largest distributing centers in the state for coal, which is received by lake, and stored in enormous quantities for shipment by rail throughout the west and north-west. The city is a port of entry, and in 1908 its imports were valued at $3,080,437, and its exports at $75,525.

In 1905 the total value of Milwaukee's factory products was $138,881,545. 25.3% more than in 1900. In the manufacture of large leather the Milwaukee is first among the cities of the United States; the total value of the city's manufactures for 1900 was $10,290,479, of which $2,112,380 was the value of malt liquors and $1,277,668 was the value of leather. In 1905 Milwaukee manufactured 17.1% of the leather products manufactured in the state and 7.4% of the entire product of the United States. Other products exceeding $1,000,000 in value were: (1899–1907), machinery, $6,274,437. More than a third of the manufacture of leather among the cities of the United States; foundry and machine
shop products ($10,232,723); iron and steel ($7,010,793); flour and
grist-mill products ($6,320,428); slaughtering and meat-pack-
ing products ($5,958,515); men’s clothing ($4,759,548); boots
and shoes ($2,929,405); electrical machinery, apparatus and sup-
plies ($2,577,220); chewing and smoking tobacco ($1,666,330)
and cigarettes ($1,546,019); furniture ($1,276,290); trunks
and valises ($1,023,310); hosiery and knit goods ($1,353,176);
confectionery ($1,379,668); stove and furnaces ($1,288,931);
leather goods, shoes and mittens ($1,207,633); structural iron
work ($1,079,720); woollen- and worsted goods ($1,007,125).

Among Milwaukee’s largest industrial establishments are:
the Pabst and Schlitz breweries, on the west side of
the city; the machine shops (53 acres) of the Allis-Chalmers
Company at West Allis, employing about 4000 men
and engines of all kinds; and the plant of the Illinois Steel
Company, at Bay View on the south side, which covers 154 acres.
The flour mills of Milwaukee have a capacity of about 12,000 barrels a
day. Two of these are on the Menominee river, the other
in the Menominee river valley the peculiar cream-coloured Milwaukee
bricks are made. North of the city on the Milwaukee river are
extensive cement works.

Newspapers. — The first newspaper in Milwaukee, the Advertisement,
began publication in 1836. The first German newspaper was
established in 1844. In 1900 there were eleven daily newspapers,
as follows: Evening Wisconsin (1847; Republican), Free Press
(1901; Independent Republican), Journal (1882; Independent
Democratic), Nation (1865; Independent), and Milwaukee
Republican, the oldest paper in continuous publication, Daily
Commercial Letter (Commercial), Reporter (legal and commercial),
Dziennik Milwaukee (Polish), Kurier Polski (1888; Republican;
Polish), Milwaukee Sentinel (1890; Independent), St Avenue
Der Herold (1854; Independent; German). Of more than a hundred
other publications thirty-two, ten monthly or quarterly and 22
weekly, were published in German. There are 5 Polish weekly
publications, 3 Bohemian, 1 Italian and one periodical for the
blind.

Population. — The population of Milwaukee in 1840 was only
1712. During the following decade there was a steady flow of
immigrants from the eastern states and from Europe, with the
result that in 1850, two years after the admission of Wisconsin
To the Union, the population was 20,061. The population at
the succeeding decennial censuses was as follows: (1860),
45,246; (1870), 71,440; (1880), 115,587; (1890), 204,468; (1900),
283,535. In 1905, according to the state census, the population
was 312,948. The fact that out of a population of 285,315 in 1900,
88,991 were foreign-born, and 235,824 were of foreign parentage,
that 53,851 were born in Germany, that 124,211 had both parents
born in Germany, and that 26,834 additional had one or the other
parent born in Germany, stamps the character of Milwaukee’s
population. The negro population in 1900 was only 862. The
proportion of illiterates is small. Of the male population, aged
10 years or more, only 3206 (2968 foreign-born whites; 194
native-born whites) were illiterate in 1900.

Government. — Milwaukee is a city government under a city charter
of 1874, providing the form of city government most common in
America, a mayor (elected biennially) and a single board
of aldermen. There are the usual administrative boards whose
members are appointed by the mayor, some of them with the
approval of the board of aldermen, though the board of school
directors is elected by direct popular vote. Two boards of
service commissioners, one for fire and police departments
and one for all other departments, have supervision over the
city’s civil service.

The assessed valuation of taxable property, in the city, in August
1906 was $301,885,127, of which $157,611,560 represented reality
and $43,273,607 personality. The valuation is about 60% of the
actual value. The tax rate for all purposes in that year was 2%–
per $100. According to a special report of the census the cost
of the city government of Milwaukee in 1906 was smaller per capita
than that of any other city in the country with a population of over
300,000. The total tax for the year was $5,836,049, and the funded debt
was $8,166,500.

History. — The first Europeans known to have visited the site
of Milwaukee were Father Jacques Marquette, the Jesuit
missionary, and his companion, Louis Joliet, who on their return
in the autumn of 1673 to the mission of St Francis Xavier at
De Pere from their trip down the Mississippi, skirted the west
shore of Lake Michigan in their canoes from Chicago northward.
Milwaukee Bay is distinctly marked in the map attributed
Marquette, the original of which is now in the Jesuit College at

Montreal, Canada; it was discovered in a convent in Montreal
by Felix Martin (1804–1886), of the Society of Jesus, and was
copied by Parkman. In 1769 La Salle and his party probably
stopped here on their way south, and in the Jesuit Relations
of that year the name Milwaukee first appears, as “Miliwke.”
This, and the various other spellings of the name, attempted
to reproduce the Indian name of the village here, which Kelton
thinks was pronounced Minnewagi and meant “there is a good
point” or “there is a point where huckleberries grow,” in allu-
sion to the fertile soil. Doubtless the cources du bois who at
this time began to frequent the Wisconsin forests, touched
at the bay many times within the succeeding years as the place
was known to be a favourite rendezvous of the Fox (or Outagamie)
Indians. In 1699–1700 Father St Cosme, a Recollect friar, was
here, finding bands of Mascoutens, Fox, Winnebago and
Potawatomis. He called the river “Melwarik,” “Melwarck” and
“Meliwark.”

For more than half a century no definite reference to the place
can be found. In 1760 its advantageous situation attracted
the adventurous trader, Alexander Henry, the first Englishman
known to have visited the spot. Three years later (1763) there
was a French fur-trading post here, but it is uncertain just when
it was established or how long it was maintained. In 1795
Jacob Vieu, a Frenchman in the employ of the North-Western
Fur Company, established a permanent post here, which seems
to have continued, under his direction, without practically no
interruption until 1820, when it was superseded by that of Astor’s
American Fur Company. Vieu built a dwelling and a
warehouse and conducted extensive trading operations. In 1818
there joined the settlement a young Frenchman named Laos
Solomon Juneau (1793–1856), who married one of Vieu’s
dughters and eventually bought out his business. Juneau
and several others who arrived at about the same time built
homes on the east side of the river near the foot of the present
Wisconsin Street. Vieu’s house and store was at this time on the
south side. Milwaukee was on the direct route of travel between Fort
Dearborn (Chicago) and the flourishing settlement at Green Bay,
and at once after the treaties between the United States and
the Menominee in 1831 and 1833 for the extinguishing of
the Indian titles, settlers began to come to the neighbourhood.
A map of 1830 shows a small settlement on “Milwauk Bay”;
and the treaty of the 8th of February 1831 speaks of the “Mil-
aukwy or Manawauky River.” Morgan L. Martin (1805–1887)
of Green Bay, a lawyer and judge, and a delegate to Congress in
1845–1847 from Wisconsin territory, explored the harbour
facilities in 1833 and made a tentative map of the region which he
called “Milwaukee.” He entered into an agreement late in the same
year with Juneau and Michael Dousman for its development.
A saw-mill was built in 1834, and settlers began to arrive. The
east side was platted in the summer of 1835, and very soon after
ward the plat of a settlement on the west side was also recorded,
Byron Kilbourn being the chief projector and proprietor of
the latter. The rival settlements, officially known as Milwaukee
East Side and Milwaukee West Side, bore the popular designa-
tions of “Juneautown” and “Kilbourn-town.” A third settle-
ment, begun on the south side by George H. Walker and known
as “Walker’s Point,” was subsequently platted independently.
The rivalry between the east and west side towns was intense; the
plats were so surveyed that the streets did not meet at the river,
and there were bitter quarrels over the building of bridges.
Milwaukee county was set off from Brown county in 1834, and
in 1836 the establishment of townships was authorized. Under
this act the east and west sides were independently incorporated
February 1837. A realization that the continuation of indepen-
dence and rival corporations retarded growth eventually led
to a compromise by which the two were united as two wards
of the same village in 1839, the autonomy of each being still
recognized by an odd arrangement whereby each maintained
practically independent management of its finances and affairs.
Walker’s Point, the south side, was annexed as a third ward
in 1845, and in 1846 the three wards were incorporated as the
City of Milwaukee, of which Solomon Juneau was elected first
MIMETITE—MIMICRY

495

mayor. The influence of this early rivalry may be seen in several provisions of the existing city charter.

About 1845 a strong tide of immigration from Germany set in, continuing steadily for a half-century. It was greatly accelerated by the German revolutionary movements of the late 'forties, which added to the city's population a considerable element of educated Germans of the upper class. From this time the Teutonic character of the population was marked. The first newspaper, the Advertiser, began publication in 1836; the first bank was established in 1837. In 1839 George Smith and Alexander Mitchell established the Fire and Marine Insurance Company Bank. As “Mitchell's Bank” this institution was known for forty years as one of the strongest banking houses west of the Alleghenies, its notes passing at par during panics in which even the government issues were depreciated. Through it the Chicago Milwaukee & St Paul and other western railways were financed. Beer was first brewed in Milwaukee in 1840. Milwaukee was connected with Chicago by telegraph in 1849, and by railway in 1856. Previous to this, however, in 1851, the first train ran over the Chicago Milwaukee & St Paul railway to Waukesha, and in 1857 trains were run over the same road to the Mississippi at Prairie du Chien.

MIMETITE, a mineral consisting of lead chloro-arsenate, (PbCl)Pb(AsO₄)₃, crystallizing in the hexagonal system and closely resembling pyromorphite (P₂O₇) in appearance and general characters. The arsenic is usually partly replaced by equivalent amounts of phosphorus, and there may thus be a gradual passage from mimetite to pyromorphite. The two species can, as a rule, only be distinguished by chemical analysis, and because of their close resemblance the less frequently occurring chloro-arsenate was named mimetite or mimetesite, from Gr. μιμητής, imitator. Crystals of pyromorphite though usually optically uniaxial are sometimes biaxial, but in mimetite this anomalous character is almost always present; a cross-section of a hexagonal prism of mimetite shows a division into six optically biaxial sectors or a complex lamellated structure. In colour mimetite is usually yellow or brown, rarely white or colourless; the lustre is resinous to adamantine. The hardness is 3, and the specific gravity 7.0-7.25. Like pyromorphite, mimetite is found in the upper parts of veins of lead ore, where it has been formed by the oxidation of galena and misplice. When found in large amount it is of importance as an ore of lead. The best crystallized specimens are those from Johanngeorgenstadt in Saxony and Wheal Unity in Cornwall. It was formerly found in considerable amount at Dry Gill in Cumberland, as six-sided barrel-shaped crystals of a brownish-red or orangeflaid colour and containing a considerable proportion of phosphoric acid; this variety has been called campylite, from Gr. καμπυλή, curved, on account of the remarkable curvature of the faces of the crystals. It is called also mimetite, (L. J. S.).

MIMICRY, in zoology, the deceptive and advantageous resemblance presented by defenceless and edible species of animals to other species of animals living in the same locality, which are harmful or distasteful and are consequently avoided by all or by a majority of the enemies of the class to which the mimetic and usually the mimicked species belong. Mimicry is a special form of protective resemblance, differing from ordinary protective resemblance as exemplified by the similarity of the resting goat-sucker to a piece of bark or of leaf-and stick-insects to the objects after which they are named, in that the imitated object belongs to the animal kingdom and not to the vegetable kingdom or to inorganic matter. Although, like protective resemblance, quite independent of affinity between the organisms concerned in the likeness, mimicry occurs most commonly between animals structurally similar, and therefore related, to one another, the relationship may be close or remote. For instance, the commonest and best-known cases are found in insects where both mimic and model may belong to the same genus, sub-family, family or order, or to different orders. More rarely it occurs between members of distinct classes of the same sub-kingdom, i.e. between spiders and ants or spiders and beetles; yet even in this case both mimic and model have in common certain fundamental structural points to which the finishing touches completing the mimetic likeness are superadded. Still more rarely mimicry exists between totally unrelated species like caterpillars and snakes or spiders and snails. But in no case does it appear that the modifications in shape and colour, which contribute to bring about a mimetic resemblance, are greater and more elaborate than those which result in the simpler examples of ordinary protective resemblance.

The principle of protective resemblance, for which the term mimicry, as above defined, was originally employed, was first explained by H. W. Bates. Subsequently the meaning of the word was extended by F. Müller to include cases of mutual resemblance between two or more noxious species inhabiting the same area. Hence the resemblances belonging to the first category are commonly termed "Batesian mimicry," and those belonging to the second category "Müllerian mimicry," or more properly "Müllerian resemblance." The difference between the two phenomena is essential and evident; but without experimental information as to palatability it is impossible to know with certainty to which of the two a particular case of mimicry is to be assigned. Over and over again extended knowledge on this point and inferences drawn from other facts have shown the certainty or probability of examples of mimicry being in reality "Müllerian," which were previously accepted without question as "Batesian." A simple illustration will serve to explain these two aspects of mimicry and to show the advantage in the struggle for existence that mimicry confers upon the species concerned.

There is a common English Syrphid fly (Eristalis tenax) known as the drone-fly from its resemblance to a large hive or honey bee. Honey bees are protected from a large number of insect enemies because they sting and are distasteful. Insect-eating birds soon learn to associate distastefulness with the size, form and colour of the bees, and consequently leave them alone after one or more trials. But flies of the drone-fly kind cannot sting, and, so far as is known, are perfectly innocuous and edible. The advantage to the fly of its deceptive resemblance to the bees is theoretically perfectly evident and practically can be demonstrated by experiment. It is in the first place a matter of common knowledge that human beings who have been taught to avoid handling bees invariably fear to touch drone-flies, unless specially trained to distinguish the one from the others. Moreover, Professor Lloyd Morgan found that young birds that had tasted and rejected workers of the hive bee as unpalatable subsequently refused to taste not only drones, which have no sting, but also drone-flies. So far as our information at present extends the resemblance between these two insects is a simple case of mimicry in the Batesian sense of the word. That is to say, an edible species is protected by resembling one that is inedible. But if it be discovered, as is possible, that the drone-fly is also inedible, then it is the species of mimicry that has been the subject of the introduction as the reason for it becomes less evident. In what way, it may be asked, are two or more distasteful species of insects, occurring in the same locality, benefited by resembling each other? The ingenious explanation suggested by Fritz Müller for similar cases met with in butterflies is probably the true answer. This explanation depends upon what is now an experimentally demonstrated fact that insectivorous birds, and probably other animals, have no instinctive knowledge of what insects are edible and what inedible. This knowledge is acquired by experience; and since it is not, at all events as a rule, taught by the first taste to any individual bird, it is reasonable to infer that a considerable amount of injury, sufficient to disable if not to kill, is annually inflicted upon insects belonging to species protected by distastefulness or kindred qualities. Now insects that possess noxious attributes, and the same is true of other animals, usually have a conspicuous warning coloration which appeals to the eyes of enemies and helps them to remember more easily the cause of an
unpleasant experience, helps in fact to establish a psychological association between a particular style of coloration and a nasty taste or a painful wound. This being so, it is evident that all the distasteful species in a given area are differently coloured, and individuals of all the species will beationally sacrificed to the experimental tasting of inexperienced foes before the numerous lessons have been learnt. But if all the species in question resemble each other the resemblance will be mutually beneficial to them because the association between the two attributes they have in common, namely distastefulness and a particular scheme of colour, will be readily established. One lesson only, instead of many, has to be learnt; and once learnt at the expense of a few individuals of one or two species it will thereafter be applied indiscriminately to all. This type of mimicry has been well defined by Professor E. B. Poulton as the unification of warning colours.

Since belief in the adequacy of the two theories, above outlined, to account for the theory of mimicry is true, it is important to test upon the testimony that can be brought forward of the usefulness of warning characters, of the deception of mimicry and of the capacity for learning by experience possessed by enemies, it is necessary to consider the various forms of mimicry that have been postulated on the basis of the observations made.

(1) In South America there are butterflies formerly grouped as Heliconiinae which are conspicuously coloured, slow of flight and abundant in individuals so as to be susceptible of easy capture. They have altogether escaped the attention of bird-hunters and are discovered independently of Messrs Bates, Wallace and Bell that they are not attacked by birds nor by many other enemies that prey upon unprotected Lepidoptera. (2) As the result of a series of trials made in Calcutta, F. Finn came to the conclusion that young birds had acquired an instinctive knowledge of the colour combinations of the distasteful insects, but that experimental tasting soon teaches them to recognize and avoid species they have previously rejected with dislike, and that having once learnt the lesson they long remember it. (3) That birds may also be deceived by insects that those they have found to be unctable has been shown by the above quoted experiment with the drone-fly and the honey-bees made by Professor Lloyd Morgan. He also found that chickens that had been given honey-bees with their wings removed attacked them and, banded black and yellow, afterwards refused to touch meal moistened with water and spread upon the same slips, although they had previously eaten it with readiness off plain coloured slips. With two mimicry experiments on birds this is not the case. The birds and yellow banded with a bitter taste also refused to touch the caterpillar of the cinnabar moth (Euchloe acutipennis), which is banded with these colours. Moreover, young birds that had been taught by experience, when caterpillars were laid before them untouchn. (4) Guy Marshall once offered to a baboon a distasteful butterfly (Acraea anomalis), holding the insect in such a way as to display its bright red and black markings to the monkey. It was taken at once. After being held for a few moments, and then let escape unharmed without trying to taste it. The butterfly is coloured like the baboon. A specimen of the mimic butterfly (Precis sesamoides) which mimics the 

Acraea was then offered in the same manner. The baboon took it, held it in its hands for a few moments, and then let escape unharmed without trying to taste it. The butterfly is coloured like the baboon.

Nevertheless, as explained above, it seems to be highly probable that anti-imitating insects and spiders, when the resemblance is dependent to a greater extent upon size, shape and movement than upon tint, have acquired their mimetic likeness especially to protect them from enemies. The dissection of birds' stomachs has shown that the family Pompilidae, flies of the family Asilidae, and so-called parastic hymenoptera of the family Ichneumonidae, as well as from other insect-eating Arthropods.

The term mimicry has also been applied to resemblances of a different kind from the two enumerated above—resemblances, that is, by which predaceous species are supposed to be enabled to live on different animals they prey upon or victimize in other ways. This to this end the resemblance may be actually to the species victimized or preyed upon or else to a species which the species preyed upon does not fear. This phenomenon is termed "aggressive mimicry" as opposed to the Batesian and Müllerian phenomena, which are termed "protective mimicry." A few possible cases of aggressive mimicry are enumerated in the following summary of some of the recorded cases of mimicry in different classes of the animal kingdom; but the phenomenon is of comparatively rare occurrence, and the supposed instances may be susceptible of other interpretations, excluding them altogether from mimicry, or bringing them under the Batesian or Müllerian interpretation of the phenomenon.

Among mammals there are no certain cases of mimicry known. It has been claimed that the resemblance between some of the Oriental tree-shrews of the genus Tupai a and squirrels comes under the category of mimicry, but the resemblance is so slight that it may be due to the likeness to approach and pounce upon small birds or other animals which, mistaking them for the vegetable-feeding squirrels, may make no effort to get out of the way. But this hypothesis cannot be confirmed by an experimental examination of the same animals.

For in the first place there seems to be no good reason for thinking that the Tupaias feed to any considerable extent upon prey of that kind, and in the second place the resemblance is due to characters that are not more susceptible to the same predators than to other animals. Hence there seems to be good reasons for regarding the likeness in question as due to similarity in habitat and not as mimetic.

In East and South Africa there is a genus of Mustelidae known as Mungos (Herpestes) which is very similar in colour and is warningly coloured with black and white bands after the colouring of the banks. There also occurs in South Africa another member of this family (Pseudoctis albina), which is very similarly coloured. It is possible the resemblance is mimetic in the Bassean sense of the word, and that the Pseudoctis, if insufficient, profits by its likeness to the highly offensive and warningly coloured Ichthyurus. But, on the other hand, Pseudoctis may itself be a protected form since sub-peri-lands are commonly found in species of the weasel tribe. If this be the case that resemblance is mimetic while the hen bird is not.

A few cases of mimicry have been recorded in birds. The common cuckoo and other species inhabiting Africa and Asia closely resemble sparrow-hawks. Some cuckoos are singular for their habit of mimicking the sounds of other birds. It may be that the young may be reared by foster-parents; and it has been suggested that the object of the likeness exhibited to the hawk is to enable the cock cuckoo either to frighten the small birds away from their one or two attempts to eat him by a hungry mongoose (Herpestes galera) which had been starved for the purpose of the experiment.

The drongo is blue and black and is, he believes, warningly coloured. The same mongoose also refused to eat a kestrel (Circus rupicola) and a hobby (Falco subbuteo), although it devoured certain
other birds that were given to it. It is clearly possible, therefore, that cucocks which mimic drongos and hawks may be protected from those enemies which find these birds distasteful.

One of the most perfect cases of mimicry in birds is presented by the laughingthrush, which resembles a pheasant for feather a shrub (Xenoprisolos polleti), from the same island. The Tylas has departed from the normal coloration of its group to take on that of the shrub, a comparatively powerful and pugnacious family, and its general coloration is that of the bush in all its unblemished. The general style of coloration of oranges is gaudy yellow and black, rendering them invisible in sunlight foliage, and quite different from the more sombre hues of the bird-shrubs; but in this case the coloration is assumed here for the birds in general, but in each of the islands name a species of orange has acquired the little peculiarities in colour of plumage possessed by the shrub-bird of the same locality. There seem to be no reasons for doubting that these are cases of genuine protective mimicry.

Apparently only the instances of mimicry known amongst reptiles occur among such; and in all the cases quoted by Wallace harmless snakes mimic venomous species. In tropical America the genus Elaps, which is both poisonous and warningly coloured, is model for several innocuous snakes. In Guatemala Elaps fulvus is mimicked by Philodryas equatorialis; in Mexico Elaps coronalis by Heloderma horridum, and Elaps pustulatus by Oxyrhyncus trigraminus. In South Africa the harmless egg-eating snake (Dassypeltis scaber) is very like the Cape adder (Bitis arietis); and in Ceylon the harmless Colubrine Lyssonolus albus is alleged to be mimicked by a similar species, but this is not certain. Considering, however, the number of venomous and innocuous snakes that occur in most tropical countries, it might be supposed that mimicry in this order of reptiles would be of common occurrence, and that it might well be the case. It must be remembered, however, that apart from size and colour all snakes resemble each other in a general way in their form and actions. They present a strong family likeness which is not found in any other terrestrial vertebrate. Anomia exist amongst the Amphibia, and can be of importance amongst the reptiles.

So close indeed is the similarity that many monkeys, apes and human beings have an apparently instinctive fear of all snakes and do not discriminate between poisonous and non-poisonous species. It has been shown, in many instances sufficiently protected by their likeness in shape to poisonous species that close and exact resemblance in colour to particular species is superfluous.

As a possibility instance of mimicry in fishes, A. T. Masterman recalls the fact that two species of weever (Trachinus draco and T. vipera), have the same habitat in British waters as certain species of sole (e.g. Solea vulgaris). The weever are poisonous and the venomous weever is actually a much smaller fish, but the two resemble each other so exactly in form and colour that it becomes a very conspicuous object. If the view that the sole is protected by the blackness of the pectoral fin resembling the blackness of the dorsal fin of the weever, be correct, these fishes furnish an instance of Batesian mimicry. Furthermore, there is a common littoral fish in the Mediterranean (Uranoscopus scaber), belonging to the same family as Trachinus, exhibiting the same habits and living on the same ground, which also has a jet black erectile dorsal fin, and is believed to be poisonous. It is possible that it may be mimicked by the true weever. The weever (Trachinus) with respect to the colour of the dorsal fin is mutually beneficial to the two fishes. So if the likeness must be regarded as an instance of Müllerian mimicry.

In the Philippines Islands several species of Longicorn of the genus Dolops mimic hard inedible weevils (Curculionidae) of the genus Phyrkynchus. The antennae of these weevils are short and end in a knob; those of the Longicorn are very much larger, but the weevil-like look is produced by the presence of a knob-like swelling upon the third joint, the terminal portion of the antenna being so extremely fine as to be almost invisible. Similar modification of this nature in the Longicorn Estigmene variabilis brings about the resemblance between this beetle and a beetle, Estigmene chinenesis, one of the Phytophaga of the family Hibidae. Numerous instances of mimicry in this order of insects have recently been brought to notice by W. C. Shelford, a large number of them being in all probability Müllerian.

Instances of ant-mimicry, unique in the method employed to bring about the resemblance, are supplied by some insects of the family Membraeidae. In one of these (Heterotus trinitodos), the dorsal area of the forepart of the thorax is developed into a plate which projects backwards over the body of the insect, which closely resembles the leg structure of the ant. The resemblance is very striking, and is produced by a patch of whitish hair on each side of the middle of the abdomen which has the effect of cutting away the parts of the segments so covered, leaving a narrow dark-coloured median area to represent the waist. This at least is the method of disguise suggested by examination of the dried insect; but representatives of the same or an allied species found in Mashonaland were observed to behave as if they were ants, the abdomen being concealed in black pigment. These parts were quite conspicuous against the green of the plants frequented by the insects, wherever the green portions were rendered invisible by the same background. Ant-mimicry is found in the case of the leaf-cutter bees of the Indian species of Mantidae. Again, several species of this order have become profoundly modified in form in imitation of inedible beetles, in the Philippines, a cricket (Scopsistis pachyrhynchos), which resembling hard and inedible weevil (Curculionidae), and Phoropsis, a kind of grasshopper similarly resembles ladybirds (Coccinellidae). A species of beetle (Carta dilatata) of this family is bored in mimicry by a well-known species of wasp (Pseudosstrangalia inornata), which has a conspicuous white patch near the tip and a patch similar in size and colour is present on the wings of the beetle, which, unlike the majority of beetles, habitually keeps its wings extended, and since these patches are exposed to the eye of the wasp, the resemblance is prolonged beyond the time when folded. The resemblance also extends to the general form of the body and to the length and thickness of the wings and antennae. The elytra are equal in size and are found to be as long in the case of the Australian hornet (Abispa australis), in the European Longicorn (Clytus arisit), and on the other hand, the elytra are of normal length and are banded with yellow stripes. The beetle, moreover, is of slender build and all its actions are suggestively wasp-like. This may, however, be an instance of Müllerian rather than of Batesian mimicry, the beetle being a species of Stenelmus, which is allied to the Borner representatives of the sub-family (Clytinae), to which Clytus arietis belongs, are all highly distasteful and are warningly coloured, as are members of this sub-family from other parts of the world.

In the Philippine Islands several species of Longicorn of the genus Dolops mimic hard inedible weevils (Curculionidae) of the genus Phyrkynchus. The antennae of these weevils are short and end in a knob; those of the Longicorn are very much larger, but the weevil-like look is produced by the presence of a knob-like swelling upon the third joint, the terminal portion of the antenna being so extremely fine as to be almost invisible. Similar modification of this nature in the Longicorn Estigmene variabilis brings about the resemblance between this beetle and a beetle, Estigmene chinenesis, one of the Phytophaga of the family Hibidae. Numerous instances of mimicry in this order of insects have recently been brought to notice by W. C. Shelford, a large number of them being in all probability Müllerian.

Instances of ant-mimicry, unique in the method employed to bring about the resemblance, are supplied by some insects of the family Membraeidae. In one of these (Heterotus trinitodos), the dorsal area of the forepart of the thorax is developed into a plate which projects backwards over the body of the insect, which closely resembles the leg structure of the ant. The resemblance is very striking, and is produced by a patch of whitish hair on each side of the middle of the abdomen which has the effect of cutting away the parts of
leaf-and-plant. The legs and lower part of the body are dark coloured, but the dorsal surface of the thorax and abdomen is coloured green and is raised so as to form a crest with jagged edges exactly reproducing the irregular margin of a fragment of leaf cut out from the flowers of the plant. In Borneo, the Homoptera is called *Issus bruchoides* mimics a species of Curculionid beetle of the genus *Alcides*.

In the Hemipterous group of the family Rhycthoea ant-mimicry is illusory. The male of a British species of Reduviid, *Atherix latericentris* (in which the forepart of the abdomen is furnished on each side with a patch of white hairs leaving a central narrow dark portion in imitation of the waist of the ant; and also an *Atherix* of the same general habits which exhibits at a glance a dear resemblance to an ant (*Polythrix gazeta*) which occurs in the same neighbourhood. Another instance in this group is supplied by a Bornean species of Reduviid which mimics a species of the genus *Bracon*, one of the parasitic Hymenoptera.

The first group of insects mentioned when in general form aculate Hymenoptera belonging to the families of bees and wasps. The changes in colour and structure required to complete the resemblance to particular species are comparatively slight and much less complicated than those needed to produce a likeness to other protected insects. Hence we find that the majority of those who mimic insects of other orders have bees or wasps for their models. Many of the Syrphidae are banded black and yellow and present a general resemblance to wasps. Especially striking is the wasp-like appearance being enhanced by a twitching action of the abdomen imitating the similar action so familiar in species of stingine hymenoptera. These flies are characterized by a peculiar method of flight. They commonly hang on the lower side of a petal and dart and swing with a snaky sort and pose themselves again. This habit, the origin of the name "hover-flies," is probably connected with their mimetic coloration. If they flew like ordinary flies their resemblance to Hymenoptera would not be so effective. In rapid flight, they can be caught on the wing by insectivorous birds or other insects; but when poised they display their coloration. When the latter is lost during flight, the rapidity of their movement defeats pursuit. The particular feature of a hover-fly is the possession of a trunkless, the drone-fly (*Eristalis tenax*), has been already referred to. But the likeness probably goes deeper than superficial resemblance that appeals to the eye; for spiders which distinguish flies from bees by touch and not by sight, treat drone-flies after touch with the same caution as they would a wasp. It is possible to convince one's self of the feebleness of this resemblance as a point of size and form, but also in the feel of its hairs or the nature of its buzz. Other flies of the genus *Volucella*, larger and heavier in build than *Eristalis*, resemble humble-bees in colour and form, and it was formerly supposed that belonging rather to the former. Sometimes Lepidoptera mimic protected members of other orders—insects such as Coleoptera, Hymenoptera and Hemiptera; but perhaps the most singular illustrations of the phenomenon known in the order are examples of those few butterflies that have been shown to imitate the heads of snakes. Professor Poultón long ago suggested, and supported the suggestion by experimental evidence on a lizard, that the larvae of two British species, *C. epenor* and *C. porcellus*, are mimetic. They exhibit certain characteristics which are imitated by the anterior extremities of their bodies which are ornamented with large eye-like spots. When the larvae are disturbed the similarity is produced with startling suddenness by the telescopic contraction of their body segments and head, the abdomen forming a triangular, pointed head with two large dorsal eyes. Subsequent observers (A. Weismann, Lady Verney) have shown by experimenting upon birds that this suggestion is correct; and Guy Marshall found that bumblebees which are afraid of snakes are also afraid of the snake-like larva of the South African *Chaetostoma lepidopteron*. Finally Shelford states that the anterior end of a Bornean species (*C. myoton*) offers a striking and detailed resemblance to the head of a snake (*Dendrophis pica*).

Instances of ant-mimicry in this order are sometimes confined to the larval stage. The early larval stage of the "Lobster Moth" (see fig.) for example, presents a general resemblance, due to a combination of shape, colour, attitude and movements, to black ants, the swollen head and the caudal disk with its two tentacles representing respectively the abdomen and antenna-bearing head of an actual ant. Ant-mimicry exists at Singapore between the larva of a Noctuid moth and the common soldier ant (*Oecophylla smaragdina*). In this case also the posterior end of the larva represents the anterior end of the ant. Another instance of mimicry affecting the larval form is supplied by the moth *Endromis nigripunctata* (Hewitson) which is a complete and convincing saw-fly. The resemblance that certain moths—e.g. *Trocchilium aspiforme*, *crabroniforme*—present to bees and wasps is effected in the main by the loss of the scales from the wings, leaving these organs and their appendages bare. It is important to note that the scales are present when the moths first emerge from the pupa-case, but are loosely attached and fall off with the first flight.

Of the multitudes of cases of mimicry between different species of Lepidoptera a few only can be selected for description. These cases, however, have a peculiar interest and importance for they have been studied in fuller detail than any others and the discovery of a particular instance in South America first suggested to Bates the method of obtaining the biometrical phenomena. One of the Amazons and in other parts of South America there are butterflies of the group *Ithomiinae* which are distasteful and have all the characters of specially protected species, being conspicuously coloured, slow flying, of a peculiar shape, hairy, etc. The wings of those species are transparent and are black- or brown-barred, the anterior wing having two black bars and the posterior one. This type of colouring is also found in genera of quite distinct sub-families and not only of *Ithomiinae*. As a result of this, and the presence of diurnal moths, all of which occur in the group *Ithoi-

The following species may be cited as instances of this latter type of pattern: *Melitaea confusa*, *Thyridia psidii*, *Eutressa timata*, *Pieris rapae*, *Hypermnestra dispar* (*Danaus plexippus*). The distinctive feature of *Danaus plexippus* is the pointed waist, which all the species belonging to different sub-families cannot be assigned to affinity. Microscopical examination of the wings, moreover, has shown that the transparency of the wings, common to all, has been slightly reduced in each of these species as compared with the general exhibiting the *Ithomiinae* type of coloration. That the Danaine and Ithomiine species are distasteful is known. *Itna*, for example, belonging to the former, has protrusible scent-emitting organs, the characteristic colour pattern, and the ability of *Danaus* to produce tufts of hair on the edge of the posterior wing. Bates offered no satisfactory explanation of the resemblance between these two genera and others of the same protected sub-families; but he ascribed the resemblance to mimicry, and placed *Ithomiinae* in the Pierine, *Dismorphia* (*Leptis* oris), to mimicry, believing *Dismorphia* to be unprotected and noting that it departed widely in the matter of coloration from typical members of the sub-family to which it was allied. At least the *Dismorphia* has been carried to a greater extreme in South America than in any other country of the world.8 Remarkable instances of it have taken place in the Ethiopian and Oriental regions. A classical and highly con-

instance of this type of pattern: *Melitaea confusa*, *Thyridia psidii*, *Eutressa timata*, *Pieris rapae*, *Hypermnestra dispar* (*Danaus plexippus*). The distinctive feature of *Danaus plexippus* is the pointed waist, which all the species belonging to different sub-families cannot be assigned to affinity. Microscopical examination of the wings, moreover, has shown that the transparency of the wings, common to all, has been slightly reduced in each of these species as compared with the general exhibiting the *Ithomiinae* type of coloration. That the Danaine and Ithomiine species are distasteful is known. *Itna*, for example, belonging to the former, has protrusible scent-emitting organs, the characteristic colour pattern, and the ability of *Danaus* to produce tufts of hair on the edge of the posterior wing. Bates offered no satisfactory explanation of the resemblance between these two genera and others of the same protected sub-families; but he ascribed the resemblance to mimicry, and placed *Ithomiinae* in the Pierine, *Dismorphia* (*Leptis* oris), to mimicry, believing *Dismorphia* to be unprotected and noting that it departed widely in the matter of coloration from typical members of the sub-family to which it was allied. At least the *Dismorphia* has been carried to a greater extreme in South America than in any other country of the world.8 Remarkable instances of it have taken place in the Ethiopian and Oriental regions. A classical and highly con-

mimetic Lepidoptera. The first is the occurrence of mimicry only in the female sex. The reason for this to be found in the greater need of protection of the female which is slower in flight than the male and is exposed to special danger of attack when resting to the females a greater dependence and the mimicry of more than one protected species by members of a single species. This is a not uncommon occurrence, and in the case of Bateesian mimicry the explanation is probably this. When an edible species is protected by a number of ant species, there is a likelihood of its increasing in numbers until it equals or surpasses the model in this respect. Were this to take place the purpose of the mimicry would be abortive, because enemies would probably not distinguish it from the model if every even small hard-shelled beetle, palatable, is advantageous there. The numbers of the mimetic species should be fewer than those of the model; and this to be achieved in some cases by the individuals of the mimic being smaller than those of the model. The structure of the model is modified to resemble the image of an ant and not the image of a beetle. Many in many cases the similarity is increased by the presence of a stripe of white hairs which has the optical effect of cutting out an extra piece of integument, exactly as occurs in the above-mentioned case. The point is that the abdomen is divided into several segments, and the structural modifications required to produce the ant appear in the region of the abdomen as the more complicated character than those of the species itself. The antennae are no longer free in the abdomen, but they are united to the body by a narrow band of skin. The second pair are held up and carried in front of the head to simulate the antennae of the ant. Added to this is the fact that the locality in which the female is commonly to the site of the animal and the large amount of protective activity of the female. The likeness presented varies considerably in degree from a general resemblance to several species, such as in the Scolytid beetle (Pachyphasma picum) of North America, to a close similarity to particular species, as in the species of the Hymenoptera, such as the species of the Salticidae, and Amycinae fortissae, one of the Thiodismatidae, which are white but live with the little red ant (Oecophylla smaragdina) and also Myrmicae providentia, which mimics the soldier ant (Hymetae splendida). The species of Clubionina, e.g., Myrmecium nigricatum, which is an exact copy of the large black ant (Pachycondyla villosa). Sometimes it is only the males of a species of beetle which mimic another species. The females of the species such as Myrmoconcha falkii, the ant and leaf-like Membracid Homopterans and the larvae of the lobster-moth (Staurus posagi), which are plant-eaters. It is probable that one explanation—that of protection—covers all cases of ant-mimicry; and this explanation lies in all probability in the immunity from the attacks of most insectivorous enemies that ants enjoy, and especially from predaceous wasps of the family Pompilidae which annually destroy thousands upon thousands of spiders to feed their larvae; and since more than one observer has testified to the fear and althoroughness these wasps show of certain other species of ant, which is mimetic to spiders. These wasps, moreover, also provision their nurseries with caterpillars, grasshoppers and other insects. Hence it may be inferred that the insects which imitate ants profit in some way from being considered ants. In the above-mentioned cases, the mimicry is a very simple case of the possession of the same type of coloration by two or more protected insects inhabiting the same district. The signification of this phenomenon, as has been already said, is not clear. When a group of beetles of the term "Mullerian mimicry" has been assigned to this and similar instances, they are not strictly speaking cases of mimicry at all but of warning coloration. Poisonous or noxious animals usually have some conspicuous attraction, such as the distastefulness of the spider, the conspicuousness, as the skunk; sometimes the emission of sound as in the rattlesnake; sometimes a combination of the two, as in the common porcupine and the large black scorpion of Africa and India. To each such protective adaptation corresponds a mimicry, or aposematic." Neither of the above-mentioned animals is mimicked; but where two or more noxious animals, inhabiting the same district, resemble each other, both being aposematic or warning differently, is an instance of Mullerian mimicry. The term "Synaposematic" is Mullerian mimicry. Finally, the likeness of an edible species to a warningly coloured inedible one in the same locality is termed "aposematic," in allusion to the pretentiousness of the warning signal. Aposematic is Batesian mimicry.
MIMNERMUS—MINA

The roots of some Brazilian species are poisonous, and that of *M. pubica*, has irritating properties. The mimoses, however, owe their interest and their extensive cultivation, partly to the beauty of their usually bipinate foliage, but still more to the remarkable development in some species of the sleep movements manifested to some extent to most of the pinnae Leguminosae, as well as many other (especially seedling) plants. In the so-called "sensitive plants" these movements not only take place under the influence of light and darkness, but can be easily excited by mechanical and other stimuli. When stimulated—say, at the axis of one of the secondary petioles—the leaflets move upwards on each side until they meet, the movement being propagated centripetally. It may then be communicated to the leaflets of the other secondary petioles, which close (the petioles, too, converging), and thence to the main petiole, which sinks rapidly downwards towards the stem, the bending taking place at the pulvinus (p in figure) or swelling base of the leafstalk. When shaken in any way, the leaves close and droop simultaneously, but if the agitation be continued, they reopen as if they have been accustomed to the shocks. The common sensitive plant of hot-houses is *M. pubica*, a native of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, but the hardly distinguishable *M. sensitiva* and others are also cultivated. *Spathodea campanulata* is known as sensitive-brier in the southern United States.

MIMULUS, in botany, a genus (nat. order Scrophulariaceae), of showy, hardy or half-hardy, herbaceous, rarely shrubby plants, natives of the extra-tropical or mountainous parts of both old and new worlds excepting Europe, but chiefly American. The plants have opposite, undivided leaves, and, generally, solitary flowers with a two-lipped, gaping corolla. The herbaceous species thrive best in damp situations; the shrubby species, of which *M. glutinosus* (formerly called *Diphacus*) is best known, are adapted for pot culture in the greenhouse. *M. lutus*, the monkey-flower of gardens, has yellow flowers with two dark marks in the mouth of the corolla; *M. Langsdorfi*, an American species, has become naturalized in water-sides in many parts of Britain.

*M. moschatus*, musk, a native of north-western America, with small, nearly regular, yellow flowers, diffuse hairy stem and hairy-scented leaves, is a well known and favourite perennial for pot culture and outside borders.

MINA, FRANCISCO ESPoz V (1781–1836) Spanish guerrilla leader and general, was born at Yodzin in Navarra on the 17th of June 1781. His father, Juan Esteban Espoz y Mina, and his mother Maria Teresa Huncay d'Arca, belonged to the class of yeomen. Mina remained working on the small family inheritance till 1808. When Napoleon endeavoured to seize Spain in that year he enlisted in the regiment of Doyle, and then passed to the guerrilla band commanded by his nephew Xavier Mina. When Xavier was captured by the French on the 21st of March 1810, seven men of the band elected to follow Francisco; and on the 1st of April of the same year the Junta of Aragon gave him the command of the guerrilleros of Navarre. His first act was to arrest and shoot at Estella, one Echevarria, who, under pretence of being a patriotic guerrilla, was in fact a brigand. The victorious government of Castile closely inquired, and by the 7th of September 1812, had been promoted to be commander-in-chief in Upper Aragon, and on the left bank of the Ebro.

In the interval he claimed that he had fought 143 actions big and little, had been repeatedly wounded with bullet, sword and lance, had taken 13 fortified posts, and 14,000 prisoners, and had never been voted above, except with the exception of the first, the synapomorphies are especially in excess of the pseudopomorphies; this appears to be the general rule elsewhere. Frequently the groups are composed solely of protected species, so far as is at present known; and sometimes of unpalatable species with exception of the model of the course. An example of the latter occurs in Singapore where the vicious red spinning-ant (Oecophylla smaragdina) is mimicked by the larva of a Noctuid moth and by spiders belonging to two distinct families. Similarly, species of the sub-order Salicaceae (Salicidaceae) or *Arumella fortis* (Thomisidae), there being no reason to suppose that either the moth larva or the spiders are protected forms. Mimetic aggregations of similar sorts to those mentioned above have been found in other animals, but the instances cited are sufficient to show how widespread are the influences of mimicry and how profoundly it has modified the insect fauna of various parts of the world.

MIMNERMUS of Colophon, Greek elegiac poet, flourished about 650–600 B.C. His life fell in the troubled time when the Ionic cities of Asia Minor were struggling to maintain themselves against the rising power of the Lydian kings. One of the extreme fragments of his poems refers to this struggle, and it speaks of the hero, offering his person with the bravery of those who had once defeated the Lydian king Gyges. But his most important poems were a set of elegies addressed to a flute-player named Nenna, collected in two books called after her name. Mimnermus was the first to make the elegiac verse the vehicle for love-poetry. He set his own poems to the music of the flute, and the poet Hipponax says that he used the melancholy *vómos kóródías,* the fig-branch strain, said to be a peculiar melody, to the accompaniment of which two human purificatory victims were led out of Athens to be sacrificed during the festival of Thargelia (Hesychius, s.v.).

Edition of fragments in T. Bergk, Poetae lyrici Graeci; see also G. von Zahnzlin, Mimnermo (1853), a study of the poet, with notes and a metrical version of the fragments.

MIMOSA (so named from the movements of the leaves in many species which "mimic" animal sensibility), a genus of the natural order Leguminosae, which gives its name to the large sub-order Mimosaceae (characterized by usually small regular flowers with valvate corolla), to which belongs also the nearly allied genus *Acacia*. They are distributed throughout almost all tropical and subtropical regions, the acacias preponderating in Australia and the true mimoses in America. The former are usually small, two-lipped (the lip usually of two parts), while the latter are of much less economic value, though a few, like the tall (*M. fergusina*) of Arabia and Central Africa, are important trees. Most are herbs or undershrubs, but some South American species are tall woody climbers. They are often prickly.
MINARET—MINAS GERAES

surprised by the French. Though some maintain that he was not at his best as a leader in battle, the strategists he was very successful, and he displayed great organizing capacity. The French authorities were compelled to allow him to levy customs dues on all goods imported into Spain, except contraband of war, which he would not allow to pass without fighting. The money thus obtained was used to pay his bands a regular salary. He was able to avoid levying excessive contributions on the country and to maintain discipline among his men, whom he had brought to a respectable state of efficiency in 1812. Mina claimed that he immobilized 26,000 French troops which would but for him have served with Marmont in the Salamanca campaign. In the campaign of 1813 and 1814 he served with distinction under the duke of Wellington. After the restoration of Ferdinand he fell into disfavour. On the 25th and 26th of September he attempted to bring about a rising at Pamplona in favour of the Liberal party, but failed, and went into exile. His political opinions were democratic and radical, and as a yeoman he disliked the hidalgos (nobles). The revolution of 1820 brought him back, and he served the Liberal party in Galicia, Leon and Catalonia. In the last district he made the only vigorous resistance to the French intervention in favour of Ferdinand VII. On the 1st of November 1823 he was compelled to capitulate, and the French allowed him to escape to England by sea. In 1830 he took part in an unsuccessful rising against Ferdinand. On the death of the king he was recalled to Spain, and the government of the regent Christina gave him the command against the Carlists in 1835, though they feared his Radicalism. By this time, years, exposure and wounds had undermined his health. He was also opposed to Thomas Zumalacarregui (q.v.), an old officer of his in the War of Independence, and an even greater master of irregular mountain warfare. His health compelled him to resign in April 1835, and his later command in Catalonia was only memorable for the part he took in forcing the regent to grant a constitution in August 1836. He died at Barcelona on the 24th of December 1836. Mina was a brave man and bold in action, and always endeavoured to keep the war against the French in 1810-12 with humanity if they had allowed him, but as they made a practice of shooting those of his men whom they took, he was compelled to retaliate. He finally forced the French to agree to an exchange of prisoners.

MINARET (from the Arabic manārat; manar or minar is Arabic for a lighthouse, a tower on which nar, fire, is lit), a lofty, turret peculiar to Mahommedan architecture. The form is derived from that of the Pharo, the great lighthouse of Alexandria, in the top storey of which the Mahommedan conquerers in the 7th century placed a small praying chamber. The lighthouse form is perpetuated in the minarets which are found attached to all Mahommedan mosques, and probably had considerable influence on the evolution of the Christian church tower (see an exhaustive study in Hermann Thiersch, Phoros Antike, Islam und Occident, 1909). The minaret is always square from the base to the height of the wall of the mosque to which it is attached, and very often octagonal above. The upper portion is divided into two or three stages, the wall of the upper storey being slightly set back behind the one below, so as to admit of a narrow balcony, from which the azan, or call to prayer, is chanted by the muezzin (muezzin, mœqîjîn). In order to give greater width to the balcony it is corbelled out with stalactic vaulting. The balconies are surrounded with stone balustrades, and the upper storeys are richly decorated; the top storey being surmounted with a small bulbous dome. The earliest minaret known is that which was built by the caliph Walid (a.d. 702) in the mosque of Damascus, the next in date being the minaret of the mosque of Tulun, at Cairo (a.d. 879), with an external spiral flight of steps like the observatory towers in Assyrian architecture. This minaret as also the example of El Hakim (906), is raised on great square towers. The more remarkable of the other Cairene minarets are those of Imam esh-Shafi (1218), Muristan al Kalaun (1280), Hassan (1354), Barkuk (a.d. 1382) and Kait Bey (a.d. 1468).

Of the same type are the two minarets added to the mosque of Damascus in the 15th century. In Persia generally circular, with a single balcony at the top, corbelled out and covered over. In India, at Ghazni, there are no balconies, and the upper part of the tower tapers upwards; the same is noticeable at Delhi, where the minaret of Kutab is divided into six storeys with balconies at each level. In the well-known tomb of the Taj Mahal the four minarets are all built in white marble, in three storeys with balconies to each storey, and surmounted by open lanterns. The minarets of Constantinople are very lofty and wire-drawn, but contrast well with the domes of the mosques, which are of slight elevation as compared with those at Cairo.

MINAS [MINOIDES] (c. 1792-1860), Greek scholar, was a native of Macedonia. During the Greek War of Independence he migrated to Paris, where he tried to enlist the sympathies of Europe on behalf of his countrymen and to promote the study of ancient and modern Greek. But his chief claim to recognition consists in his discovery of two important MSS. (amongst others) in the monastery of Mt Athos during his exploration of the libraries of Turkey and Asia, at the instance of M. Villenain, minister of public instruction in France. One of these contained the last part of a treatise on the Refutation of all Heresies, now generally admitted to be the work of Hippolytus (q.v.), the other the greater portion of the Fables of Babrius.

MINAS GERAES (i.e. "general mines"), popularly Minas, an inland state of Brazil, bounded N. by Goyaz andBahia, E. by Bahia, Espirito Santo and Rio de Janeiro, S. by Rio de Janeiro and Sao Paulo, and W. by Sao Paulo, Matto Grosso and Goyaz. It is very irregular in outline and covers an area of 221,861 sq. m. upon the great Brazilian plateau. Among the Brazilian states it is fifth in size and first in population—3,184,099 in 1890, and 3,594,471 in 1900.

The surface of Minas Geraes is broken by mountain ranges and deep watercourses, the latter forming fertile valleys shut in by partly barren uplands, or campos. The reckless destruction of forests along the watercourses also adds to the barren aspect of the country. The principal mountain ranges are the Serra da Mantiqueira on its southern frontier and its N. extension, the S. do Espinhal, which runs parallel to the Serra do Mar, or coast-range, and separates the inland or campo region from a lower forested zone between the two ranges. Most of the wooded district south of the Mantiqueira belongs to the states of Sao Paulo and Rio de Janeiro, but east of the Espinhal it belongs to Minas Geraes and extends eastward to the Serra das Aymores, on the frontier of Espirito Santo. This zone has an abundant rainfall, dense forests and a fertile soil. It is drained by the Doce, Mucury, Jequitinhonha and Pardo, which have their sources on the eastern slopes of the Espinhal and cut their way through the Aymores to the sea. The tributaries of the Rio Doce cover the slopes of the Serra do Espinhal for a distance of 200 m. The southern part of this region is well populated, and is covered with coffee and sugar plantations. On the western frontier a northern extension of the great central chain of Goyaz forms the water-parting between the drainage basins of the Sáo Francisco and Tocantins, and is known at different points as the Serra do Paranã, Serra de Sao Domingos and Serra das Divisões. South-east of this chain, between the headwaters of the Paranã and Sáo Francisco, are the Serra da Canastra and Serra da Matta da Corde, an irregular chain of moderate elevation running north and south. The highest elevations in the state, so far as known, are Itatiya (8,908 ft.) in the Serra da Mantiqueira, and Caraça (6,414 ft.), near Ouro Preto, in the Serra do Espinhal. The hydrography of the campo region of Minas Geraes is extremely complicated. The Mantiqueira-Espinhal chain shuts out the streams flowing directly east to the Atlantic, and the boundary ranges on the west shut out the streams that flow into the Tocantins, although their sources are on the actual threshold of the state. Between these two mountain chains the head streams of the Paranã and Sáo Francisco are intermingled—the one flowing inland and
southward to the great La Plata estuary, the other northward and eastward across the arid highlands of Brazil to the Atlantic coast in 10° 30' S. lat. Less than 100 m. from the city of Rio de Janeiro and about 60 m. from the coast is the source of the Rio Grande, the larger of the two rivers that form the Paraná. It rises near the peak of Itatiaya, on the northern slopes of the Mantiqueira, and flows north-west and west across the Minas plateau, receiving several large tributaries from the south. North and parallel with its course is a low watershed, which separates its drainage basin both from that of the São Francisco and from that of the Paraná, the northern confluent of the Paraná. The latter rises on the western slopes of the Serra da Matta Corde, and one of its northern tributaries has its source in a "knot" of the Serra dos Pyreneos, from which streams flow eastward to the São Francisco and northward to the Tocantins. The central and greater part of the state, however, is included in the drainage basin of the upper São Francisco. Its source is in the Serra da Canastra, and its general course across the state is north by east, during which it receives the Paracatu, Uruçuca, Pardo and Carinhannah from the west and the Verde Grande and das Velhas from the east. Part of these rivers are navigable for small steamers; the upper São Francisco is of great importance in the development of Central Brazil. All these rivers of the Brazilian plateau are interrupted by falls and rapids. The climate of Minas Geraes is characterized by high sun temperatures and cool nights, the latter often dropping below the freezing point on the higher campos. The mean annual temperature is about 85° in the São Francisco valley, 77° on the campos of the S.E., and 70° on the campos of the W. The year is divided into two seasons—wet and dry—the former lasting from November to May. This division is not so clearly marked in the south, especially in the "matta" (forest) regions, where the rainfall ranges from 50 to 65 in. There is much malaria in the wooded districts of the east and on the higher campos, where the daily extremes of temperature are great, lung and bronchial diseases are common. Some of the high plains, however, as at Barbacena, serve as health resorts for the coast districts.

Minas Geraes is a mining state, though the mining industry has lost much of its importance through the decline in the output of gold and diamonds. Gold is widely diffused, and abandoned "washings" all over the state show how general the industry was at one time. There were in 1908 five deep mines worked by English companies and one by a French company. One of these, the Morro Velho mine, belonging to an English company, is not only the deepest gold mine in existence (over 2000 ft.), but it has been worked since 1725, and since 1835 by its present owners. Silver is not mined by itself, but is found in combination with gold. In 1908 a rich goldfield was discovered in the northern part of the state, 5 m. from Montes Claros, in the valley of the Verde Grande River, and attracted large numbers of miners. There are many rich deposits of iron ores in the state, but they only produce a small quantity of charcoal iron for local consumption. Manganese ore is mined for export, and bismuth is reported to have been discovered. Minas Geraes is most widely known for its diamonds, which are found in widely separated parts of the state. The largest and most productive field is that of Diamantina (q.v.) on the head-waters of the Jequitinhonha River, where diamonds were discovered about 1775, and where the celebrated "diamond reservation"—an oval-shaped territory 8 leagues wide by 16 leagues long (Mawe), with Tejucu, now Diamantina, very nearly in the centre—was established in 1730. The mines became crown property, gold-mining was forbidden, and no one was permitted to enter the reservation without a licence. The state monopoly was abolished in 1832, and mining has since been carried on by private enterprise. John Mawe estimates that the annual product was 1000 oz. during the first twenty years, and Castelnau estimates the value of the total output down to 1840 at 300,000,000 fr. No estimate can be made of the contraband, which must have been large. A great decline in the output occurred during the last half of the 19th century; but a new field was discovered in 1908 at Abbadia dos Dourados, in the western part of the state. Other valuable stones, the topaz, chrysolite, aquamarine amethyst and tourmaline are found.

Agriculture and grazing have become the main dependence of the population—the former in the lower, forested region of the south-east, where coffee and sugar-cane are the principal products, and the latter on the higher campos and river valleys, and on the mountain slopes, where large herds of cattle are to be found, and milk, butter and cheese are produced. The shipping of fresh milk to Rio de Janeiro and butter-making are comparatively new industries. The river valleys of the campo region are also cultivated to some extent. Among the general products are Indian corn, tobacco, mandioca, beans, pork and cotton. Wheat has been produced in some localities, but not on a paying basis, and experiments have also been made with tea. There is a large variety of fruits, and the cultivation of grapes for wine-making is developing into a profitable industry. Railway communication with Minas Geraes includes the following lines: the Central do Brazil (formerly known as the Dom Pedro II.), which starts from Rio de Janeiro and penetrate nearly to Pirapora (its objective point), at the head of navigation of the São Francisco River, and branches into neighbouring districts; the Leopoldina, from Rio de Janeiro into the forested region of eastern Minas; the Minas and Rio, from Cruzeiro, on the São Paulo branch of the Central do Brazil, into southern Minas; the Mogiana, from Campinas, São Paulo, and runs to Uberaba in western Minas, and is intended to cross into Goyas; and the Bahia & Minas, from the port of Caravelas, in southern Bahia, which runs a short distance into Minas Geraes, and is planned to extend to Philadelphia and beyond. Another line from the port of Victoria, Espirito Santo, northward to Diamantina, Minas Geraes, was under construction in 1908. River transport has some local value on the upper São Francisco and its larger tributarics, and this will be greatly increased when the Central do Brazil railway reaches the head of navigation on that river.

The population of Minas Geraes is chiefly of Portuguese origin, which has been constantly strengthened by immigrants from the mother country. A considerable admixture from other nationalities has resulted from the influx of mining adventurers, and some German colonies have been established in the state. The negro population is large, and there is a still larger contingent of mixed races. The capital is Bello Horizonte (q.v.), or Cidade de Minas; other important cities and towns are: the former capital, Ouro Preto, Barbacena, Diamantina, Baependy (pop. 22,517 in 1890), on the head-waters of the Rio Verde, the centre of a rich tobacco-producing district; Curvelo (8071), north of Sabará in the Rio das Velhas Valley, the centre of a cotton-growing district and cotton manufactures; Entre Rios (7681), in the coffee district of south-east Minas; Januaria (5888), a river port of the São Francisco in northern Minas; Juiz de Fora; Mariana (4751), an episcopal town east of Ouro Preto, Mar de Hespanha (18,712), the centre of a productive and populous agricultural municipality of south-east Minas; Paracatu (21,418), an important commercial centre of western Minas near the Goyaz frontier; Queluz (12,000), on the Central do Brazil railway; Congonhas do Campo (10,903), in the municipality of Queluz, celebrated for its miracle-working image, its great church and chapels, and the pilgrimages to its shrine; Sabará (4590), a railway station on the Central do Brazil, and port on the Rio das Velhas; Congonhas de Sabará (14,666), in the municipality of Sabará, where the celebrated Morro Velho gold mine is situated; São João d'El-Rei (15,280) an important commercial mining and pastoral centre, near the Rio das Mortes, connected with the Central do Brazil railway by a branch called the Oeste de Minas; and Uberaba (12,231), a commercial town of the western camps of Minas, connected with São Paulo by the Mogyana and São Paulo railways.

Minas Geraes was first explored by Fernando Dias Paes Leme between 1664 and 1677, though he was not the first European to penetrate it. The discovery of gold in 1602-1655 by bands of adventurers from the São Paulo settlements, led to every occupation and profession being abandoned in the mad rush for the new mines. Minas Geraes at first formed part of the
MINBAR—MINEHEAD
503
captainia of São Paulo, but in 1720 it became a separate government and was brought more directly under the Portuguese crown. The arbitrary restrictions imposed upon the colonists aroused dissatisfaction among them and eventually led to conspiracy in 1789, inspired by a fear that the Portuguese government was about to enforce the collection of its "fifth" of the mining output, which had largely fallen into arrears. Among the conspirators was one José Alves Maciel, who had just returned from France where he had met Thomas Jefferson and had become infected with French revolutionary ideas. A number of residents became involved, among them the poet Thomaz Antonio Gonzaga. Reckless talk in public places led to the arrest of the conspirators. Only one was executed, a poor, uneducated subaltern militia officer Joaquim José da Silva Xavier, nicknamed O Tiradentes (the Tooth-puller), the others being imprisoned or banished. Tiradentes has since been glorified as the pro-martyr of Brazilian independence. In 1822 Minas became a province of the empire created by Dom Pedro I, though a revolutionary outbreak had occurred in Ouro Preto the year before. In 1842 a long series of quarrels in Rio de Janeiro culminated in a revolution in Minas Geraes and São Paulo, which was suppressed at Santa Luzia, Minas Geraes, on the 20th of August of that year. The abolition of slavery in 1888 caused much discontent among the planters and in the following year Minas Geraes promptly adhered to the declaration of the republic in Rio de Janeiro.

MINAR, or MIMBAR, a term in Mahomedan architecture for the pulpit in a mosque from which the Friday or Mahomedan Sabbath sermon is given (see PULPIT).

MINBU, a district and division of Upper Burma. The district has an area of 3,299 sq. m., and a population (1901) of 233,377, showing an increase of 8% in the decade and a density of 71 inhabitants to the sq. m. The district may be said to consist of low plain-land towards the Irrawaddy, and of undulating country inland rising higher and higher westwards towards the Arakan hills. Between the Arakan plain and the Arakan range is a distinct line of hills running north and south, and usually called the Nwa-Madaung hills. The submontane valleys are largely cultivated, but are deadly except to those born in them. The chief streams besides the Irrawaddy are the Môn, the Maung, and the Salin, which are largely used for irrigation. At Minbu town the Irrawaddy is 3 miles wide, with many islands and sand-banks. There are considerable fisheries along the Irrawaddy and on the Paunglin lake, which is a lagoon fed from the Irrawaddy. The rights are sold yearly by public auction, and realize an average of £1,000. Oil has been discovered near the mud volcanoes of Minbu, but it seems to lie at too great a depth to be profitably worked.

There is a large area of reserved forest in the district. The chief crops raised are rice, gram, millet, beans, peas, sesame and tobacco. The betel-vine is largely cultivated along the Môn River. The district, which was in a chronically disturbed state before annexation, was not restored till two years afterwards, many officers losing their lives, among them Phayre, the first deputy-commissioner. The annual rainfall varies greatly over the district. It is very considerable on and under the Arakan Yomas, and very slight towards the Irrawaddy. The thermometer rises to over 100° in the hot months, and the mean of minimum in December is about 40°. MINBU, the district headquarters, stands on the Irrawaddy. It had a population of 5780 in 1901. The river steamers in the dry season can come no nearer than two miles to the south of the town.

The division includes the districts of Thayetmyo, Pakôkku, Minbu and Magwe. It has a total area of 17,172 sq. m., and a population (1901), of 1,076,280, showing an increase of 8% in the decade and giving a density of 63 inhabitants to the square mile. It bestrides the Irrawaddy. (J. G. Sc.)

MINCHINHAMPTON, a town in the Stroud parliamentary division of Gloucestershire, England, 14 m. S.E. of Stroud. Pop. (1901), 3737. It lies high on a slope of the Cotswold Hills; Minchinhampton Common being a fine open upland. The church of Holy Trinity, largely reconstructed, contains many brasses and memorials. The manufacture of woolen cloth is the long-established staple of Minchinhampton. Prehistoric remains have been discovered on the common, and earthworks are also seen; while the name of Woeful Dyeve Bottom, a neighbouring valley, perhaps indicates the scene of a defeat of the Danes (c. 918).

MINDEN, a town of Germany, in the Prussian province of Westphalia, 44 m. by rail to the W.S.W. of Hanover, on the left bank of the Weser, which is spanned by two bridges. Pop. (1905), 25,428. The older parts of the town retain their narrow and crooked streets. The cathedral tower dating from the 11th century, illustrates the first step in the growth of the Gothic spire in Germany. The nave was erected at the end of the 13th century, and the choir in 1377-1379. Among the chief edifices are the old church of St Martin; the town hall, with a Gothic façade; the law courts and the government offices, constructed, like many of the other buildings, of a peculiar veined brown sandstone found in the district. The town has a statute of Frederick William I, the great elector of Brandenburg. Minden contains a gymnasium and several hospitals, besides other charitable institutions. Its industries include linen and cotton weaving, dyeing, calico printing, brewing, ship-building and the manufacture of tobacco, glass, soap, chocolate, leather, lamps, chicory and chemicals. There is also some activity in the building of small craft.

Minden (Mindun, Mindo), apparently a trading place of some importance in the time of Charlemagne, was made the seat of a bishop by that monarch, and subsequently became a flourishing member of the Hanseatic League. In the 13th century it was surrounded with walls. Punished by military occupation and a fine for its reception of the Reformation, Minden underwent similar trials in the Thirty Years' War. In 1528 the bishopric was converted into a secular principality under the elector of Brandenburg. From 1807 to 1814 Minden was included in the kingdom of Westphalia, and in the latter year it passed to Prussia. In 1876 the fortifications, which had been razed by Frederick the Great after the Seven Years' War, were restored and strengthened, and as a fortress of the second rank it remained the chief military place of Westphalia down to 1873, when the works were finally demolished. About 3 m. to the south of Minden is the so-called "Porta Westfalica," a narrow defile by which the Weser quits the mountains. The bishopric of Minden embraced an area of about 400 sq. m. and had about 70,000 inhabitants.

The battle of Minden was fought on the 1st of August 1759 between the Anglo-Allied army commanded by duke Ferdinand of Brunswick and the French under Marshal Coutades, the latter being defeated. The most brilliant episode of the battle was the entire defeat of the French cavalry by the British infantry (with whom there were some Hanoverian troops), but Minden, though it is one of the brightest days in the history of the British army, has its dark side also, for the British cavalry commander Lord George Sackville (see SACKVILLE, IVSCOUNT) refused to give battle to his own men; several times sent by Duke Ferdinand, and thereby robbed the victory of the decisive result which were to be expected from the success of the infantry. For an account of the battle and of the campaign of which it is the centre, see SEVEN YEARS' WAR.

See Stoy, Kurzer Abriss der Geschichte Mindens (Minden, 1879); Bolische, Skizzen aus Mindens Vergangenheit (Minden, 1897); Holscher, Beschreibung des vormaligen Bistumes Minden (Münster, 1877).

MINEHEAD, a market town and seaside resort in the Wellington parliamentary division of Somersetshire, England, 185 m. W. by S. of London by the Great Western railway. Pop. of urban district (1901), 2511. The town has three parts: the Upper, built on the sides of a lofty foreland known as North Hill; the Lower; and the Quay Town, with many ancient houses, stretching for about a mile beside the harbour. It is much visited for the sake of its mild climate, the grand cliffs, moors and hills of the neighbourhood, and the beach, admirably suited for bathing. St Michael's, the parish church, has a striking Perpendicular tower, an arch of carved oak dividing its nave and
chancel, a magnificent rood-loft, and a 13th-century monument doubtfully described as the tomb of Bracton, the famous lawyer, whose birthplace, according to local tradition, was Bratton Court in the vicinity. Coachors for Forlock and Lynton start from the town.

There is no evidence of the existence of Minehead (Manneheu, Manchelf, Mynchevel) in Roman or Saxon times. The town owed its origin and growth to its position on the shores of the Bristol Channel, and its good harbour developed an overseas trade with Bristol, South Wales and the Irish ports. The De Mohun family were overlords of the town from 1086 to the 14th century, when they were followed by the Luttrells, who are the present owners. It is possible that Minehead had a corporate existence during the 13th century, as certain documents executed by the portreeve and burgesses at that date are preserved, but no record of the grant of a charter has been found. A charter of incorporation given by Elizabeth in 1538 vested the government in a portreeve, a steward and twelve burgesses, the continuance of the corporation being subject to the port and harbour being kept in repair. This condition being unfulfilled, the charter lapsed in the reign of James I., and an attempt to obtain its renewal in the 18th century failed. The corporation was replaced by two constables chosen annually in the borough and the manor until 1804, when a further district council was appointed. The borough returned two members to parliament from 1558 until disfranchised by the Reform Act of 1832. A weekly market on Tuesdays and a fair (Sept. 29 to Oct. 2) were held by the lord of the manor from the 15th century, but the date of the grant has not been found. In 1465 a second annual fair on the ist of May was granted by Edward IV., which is still held on the Wednesday in Whitsun week. The other fair has been discontinued, and the market day has been changed to Wednesday. During the 16th, 17th and 18th centuries Minehead had a considerable coastwise trade in wool, grain and wine, but began to decline owing to the migration of the woollen industry to the north of England, and to the decay of the herring fishery. A renewal of prosperity began when it acquired a reputation as a watering-place.

See Victoria County History: Somerset; F. Handcock, Parish and Borough of Minehead (1903).

MINEO, a town of the province of Catania, Sicily, 34 m. S.W. of Catania by rail. Pop. (1901) 33,963. It occupies the site of the ancient Menaenum, founded by Ducetius in 459 a.c. There is some doubt as to whether this town was also the birthplace of Ducetius, owing to confusions in nomenclature (see E. A. Freeman, History of Sicily, ii. 361). Remains of ancient fortifications still exist, though it seems uncertain whether they are of Greek or of Byzantine origin (Notizie degli Scavi, 1899, p. 70). Four miles to the north is the Lacus Pelorium, a small lake in a crater, which still sends up carbonic acid gas. By it was the temple of the Palici, twin Sicel gods, the most holy place in Sicily, where an oak taken was especially binding, and an inviolable asylum for fugitive slaves. There is now nothing to suggest twin deities; in ancient times there were probably two craters, whereas now there is only one. It was here that Ducetius, a few years later, founded a new seat for his power, the city of Palica.

MINERAL DEPOSITS. The subject of mining (q.v.) can only be properly understood after the general features of mineral deposits have been elucidated. In this article deposits of all kinds of useful minerals are included, whether they are metalliferous or earthy. In general practice it is customary to treat the former under the name "ore-deposits" and the latter as the "non-metallics." This is warranted because in a large degree different geological problems are presented and different methods of mining are pursued. Nevertheless there are other important similar or common features and they may be classified together without great disadvantage.

The word "ore" is used in several meanings, each of which depends for its special significance upon the connexion. In purely scientific applications "ore" implies simply a metalliferous mineral, and in that sense it appears in works on mineralogy and petrology. In former years and in connexion with practical mining an ore was defined as a compound of metal or of metals with one or more non-metallic compounds, called mineralizers, of which oxygen and sulphur were usually the chief. The ore must, in addition, be sufficiently rich to be mined at a profit. Native metals not being compounds were not considered ores. The product of the copper mines on Keweenaw Point, Lake Superior, was, and to a great extent is, called copper rock rather than copper ore, and native gold in quartz is often described as gold quartz rather than gold ore, but these restrictions are gradually disappearing. An ore may therefore be defined as a metalliferous mineral or aggregate of metalliferous minerals mingled with a greater or less amount of barren materials called the "gangue," and yet rich enough to be mined at a profit. When not proved to be sufficiently rich to be remunerative, the aggregate is called "mineral." The "mineral" of to-day may be changed by the advent of a railway or the rise in the price of metal into the "ore" of to-morrow. The question has repeatedly appeared in litigation involving contracts or property rights.

Since the greater number of the ores are believed to have been precipitated from aqueous solution, or to have been otherwise formed through the agency of water, the term "ore-deposit" has resolved; and inasmuch as nearly all the useful minerals owe their origin to the same agent, the term "mineral deposit" is equally well justified. A few, however, have been produced in a different way, such as certain iron ores of igneous origin; certain igneous rocks used for building stone, as in the case of granite; and the accumulations of vegetable material in coal beds. These latter, the igneous masses and the vegetable accumulations, being placed in two divisions by themselves, we may group the larger number into two main classes, depending on their precipitation from solution or from suspension. In the case of solution we will further subdivide on the place, and therefore in large part on the cause, of precipitation, since these are the questions chiefly involved in actual development.

Especially in connexion with ore-deposits widening experience has modified the older conceptions of relative values in the several types. In the early days of geology, Cornwall and Saxon Saxony were the two regions where the most active and influential students of ore-deposits were trained and where the principal books relating to them originated. The pronounced and characteristic fissure veins of England and Germany became the standards to which the phenomena met elsewhere were referred, and by means of which they were described. This particular form, the fissure vein along a fault, assumed a predominating importance, both in the thought and in the literature of the day. Widening experience, however, especially in the Cordilleran region of North America, in the Andes of South America, in Australia and in South Africa, has brought other types into equally great and deserved prominence. Comprehensive treatment to-day therefore dispels somewhat from earlier standards.

As far as analyses and estimates permit, the common useful metals occur in the earth's crust in approximately the following percentages:—

By the letter x is meant some undetermined digit in the corresponding place of decimals. Apart from aluminium, iron, manganese and nickel, the figures show how small is the contribution made by even the commoner metals to that portion of the mass of the globe which is open to observation and investigation.

As compared with the earth's crust at large certain of the metals are known to be locally present in favourable, usually igneous, rocks in richer amounts, according to the following determinations which have been made upon large samples of carefully selected materials. Copper, 0.000%; lead,
MINERAL DEPOSITS

ores, silicates, arsenic, and antimony, sometimes necessary and of great importance and of which is the depth to which it extends. This remained a somewhat indefinite feature until L. M. Hoskins showed mathematically that cavities in the finest rocks became impossibilities at about 10,000 metres. Down to some such limiting depth as an extreme the ground-water was believed by many to descend; to migrate laterally; to experience the normal increase of temperature with depth; the effect of pressure; the increased efficiency as a solvent peculiar to the conditions; and finally with a burden of dissolved gange and ore to rise again, urged on by the "head" of the descending column. In its ascent it was supposed to fill the veins. Mining experience has, however, indicated that the known groundwaters are comparatively shallow and seldom extend lower than 500-600 metres. It is conceivable that during faulting and the formation of great dislocations this upper reservoir might be tapped into greater depths and set in limited circulations through deeper-seated rocks. But so far as these objections have weight they have greatly restricted the vertical range of the meteoric ground-waters as they were formerly believed to exist.

In contrast with the meteoric waters outlined above, other waters are believed by many geologists to be given off by the deep-seated intrusive rocks, and are generally called magmatic. We are led to this conclusion by observing the vast quantities of steam and minor associated vapours which are emitted by volcanoes; by the difficulty of accounting in any other way for the amount and composition of certain hot springs; and by the marked and characteristic association of almost all ore-deposits in the form of veins with eruptive rocks. That igneous masses have been connected with the formation of veins is further brought out by the following general consideration, which has hitherto received too little attention. Aside from pegmatites, veins rich enough to be mined and even large veins of the barren gangue-minerals are exceptional phenomena when we compare the regions containing them with the vast areas of the earth which have been carefully searched for them and which have failed to reveal them. As components of the earth's crust the useful metals except iron and aluminium are extremely rare. Some sharply localized, exceptional, and briefly operative cause must have brought the veins into being. The universal circulation of the ground-water of meteoric origin fails to meet this test, since if it is effective we ought at least to find veins of quartz and calcite fairly universal in older rocks. In North America, moreover, by far the greater number of veins which have been studied date from the Mesozoic and Tertiary times. The ore deposits of older date are chiefly of iron and manganese and can be satisfactorily explained in many cases by the reactions of the vadose region, or by crystallization from molten masses.

In summary it may be stated that the meteoric waters are of great importance and of unquestioned efficiency in the shallow vadose region, or, as named by C. R. van Hise, "the zone of weathering." In it the disintegration of rocks exposes them to the searching action of solutions, and the portions of ore-bodies already deposited undergo great modifications. The deeper and far more movable ground-water probably extends to but moderate depth and is chiefly affected as regards movement by the head of waters entering heights of land and by local intrusions of igneous rocks. It is very doubtful if the normal increase of temperature with depth produces much effect. The meteoric waters are of altogether predominant importance in all surface concentrations of ore and mineral character. The magmatic waters, on the other hand, seem to be of paramount importance in producing the deposits of ores in the contact zones next eruptives, and in the formation of veins which are reasonably to be attributed to uprising heated waters in regions of expiring vulcanism. They start with their burden of dissolved metals and minerals under great heat and pressure, amid conditions favouring solution, and migrate to the upper world into cooling and greatly contrasted conditions which favour precipitation. Undoubtedly they are responsible for many low-grade deposits.
which have later been enriched by the action of descending meteoric waters. They are more copiously yielded, so far as we may judge, by acidic magmas than by basic ones.

The natural waterways are furnished by the cavities in rocks. They vary in size from very minute pores, where movement is slow because of friction, but where solution takes place, through others of all dimensions up to great fault-zones. The smallest cavities are the natural pores of minerals; cleavage cracks; the voids along the contacts of different minerals; cracks from crushing during dislocation; cellular lavas; volcanic necks; voids among the grains, pebbles, or boulders of fragmental rocks; joints; caves, and faults. So far as waters have deposited ores and yielded ore-bodies by subterranean circulations the latter are guided by some such controlling influence as these in all cases, and they will be selected as the governing principle in a large part of the scheme of classification. The types will be reviewed in the following order:
